<b>VCID</b>	system-wide unique ID of a device
<b>GUID</b>	Unique ID of device class
<b>API</b>	Application Programming Interface

## 2 System Overview

The VCI (Virtual Communication Interface) is a driver that provides common access to the different devices by HMS Industrial Networks for applications.

The VCI .Net adapter is based on the VCI, that provides an interface based C++ API. In this guide the .NET programming interface Ixxat.Vci4.dll is described.

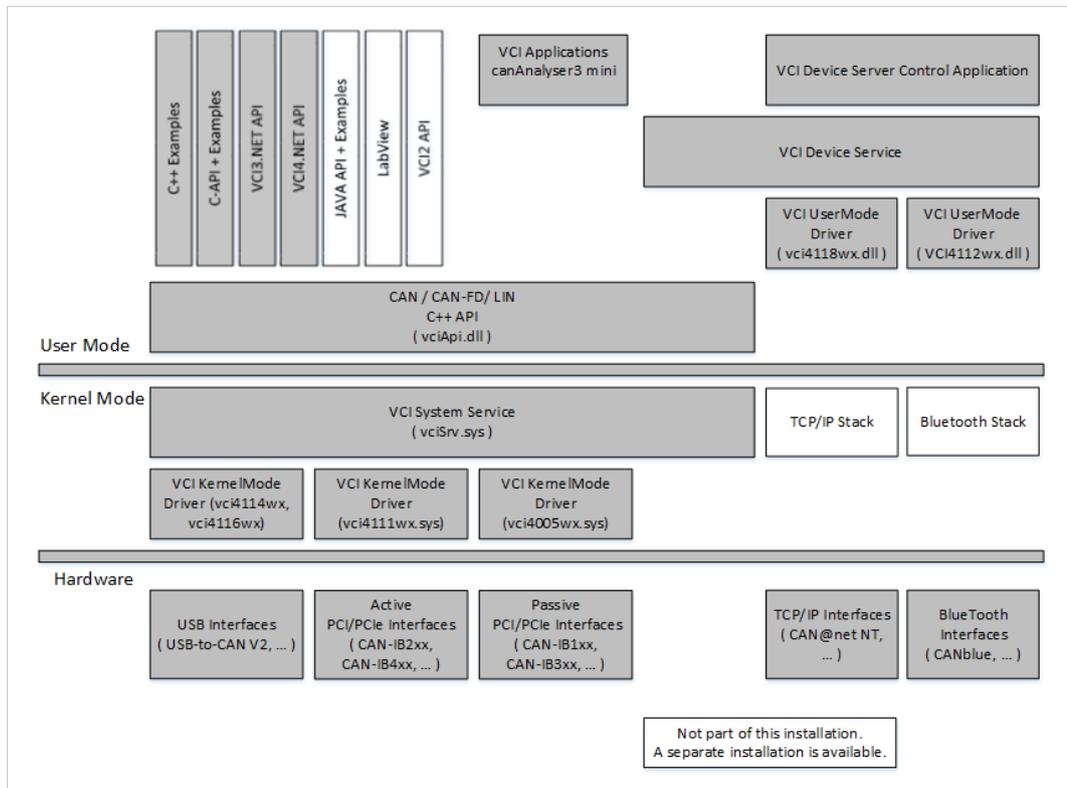

Fig. 1 System components

## 2.1 Components of the VCI V4 .NET Adapter

The VCI .NET adapter contains a set of .NET assemblies for .NET 3.5 and for .NET 4.0 and higher, that are located in the corresponding subdirectories NET35 and NET40. If included via NuGet the correct version is copied to the project directory. Except for the dependencies to corresponding system assemblies, the assemblies have the same functionality. The adapter works on top of VCI3 and VCI4 installations.

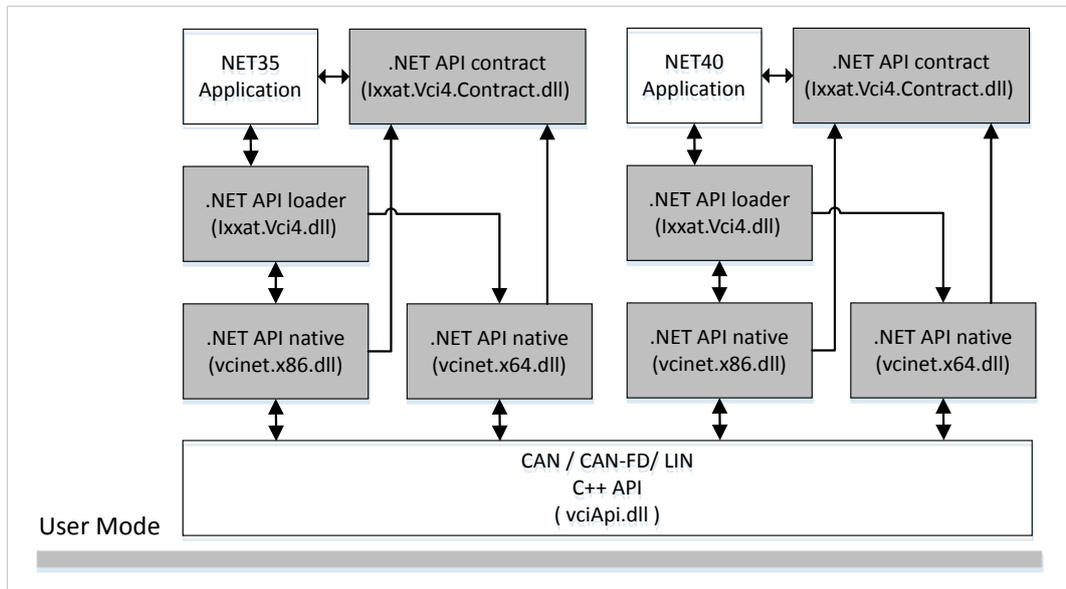

Fig. 2 VCI3 .NET adapter

- *Ixxat.Vci4.Contract.dll*: contains basic class and interface declarations, defines the interface (contract) between VCI .NET adapter and application.
- *Ixxat.Vci4.dll*: contains the minimal loader, which loads depending on the processor architecture in use the corresponding native component (*vcinet.x86.dll* or *vcinet.x64.dll*). Simplifies the deployment of applications, that are compiled independently of the architecture (AnyCPU).
- *vcinet.x86.dll*: native component for x86 systems
- *vcinet.x64.dll*: native component for x64 systems

### Differences to VCI .NET API Version 3:

- simplifies the deployment and reduces dependencies between various interfaces, since there is no installation within GAC
- different declarations due to the moving of the interfaces in *Ixxat.Vci4.Contract.dll* and the implementation of the loader *Ixxat.Vci4.dll*
- additional interfaces *ICanChannel2*, *ICanSocket2*, *ICanScheduler2*, *ICanMessage2* and value types *CanBitrate2*, *CanFdBitrate* and *CanLineStatus2* for CAN FD support

## 2.2 Legacy Interfaces

### 2.2.1 VCI V3

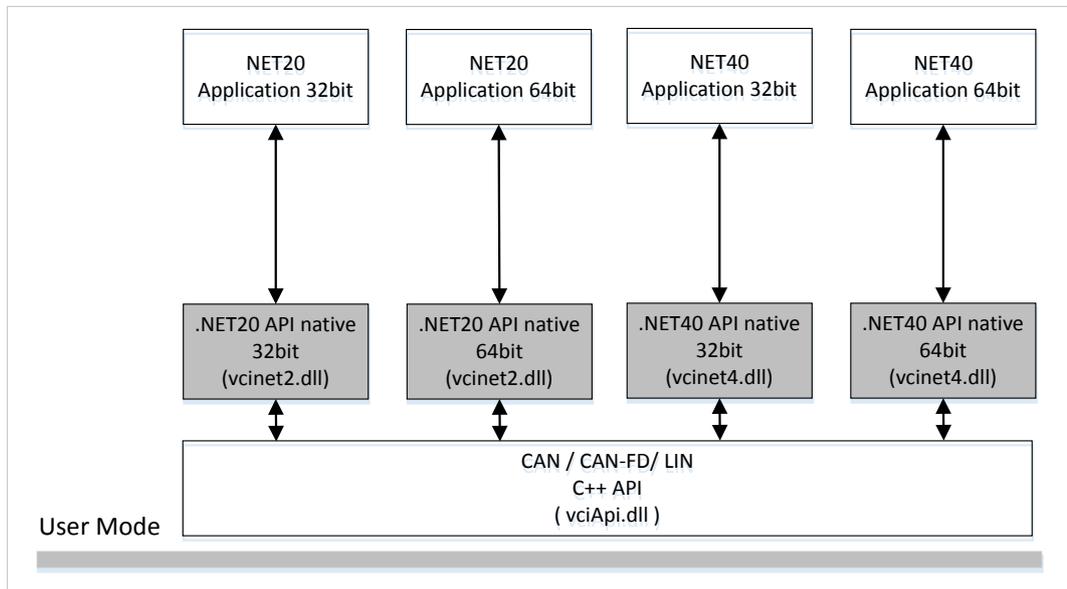

Fig. 3 VCI V3 interfaces

Due to compatibility reasons the interfaces used with VCI V3 are also installed with the VCI V4. HMS Industrial Networks recommends using only the VCI .NET API version 4 for new developments. If the integrated VCI V3 adapter is used for existing VCI V3 applications see chapter [Porting the Applications, p. 10](#) for further information.

### 2.2.2 VCI V2

To use an existing VCI V2 based application with the VCI V4 the VCI V2 adapter must be installed. For further information observe the *ReadMe* file in the VCI V2 installation folder.

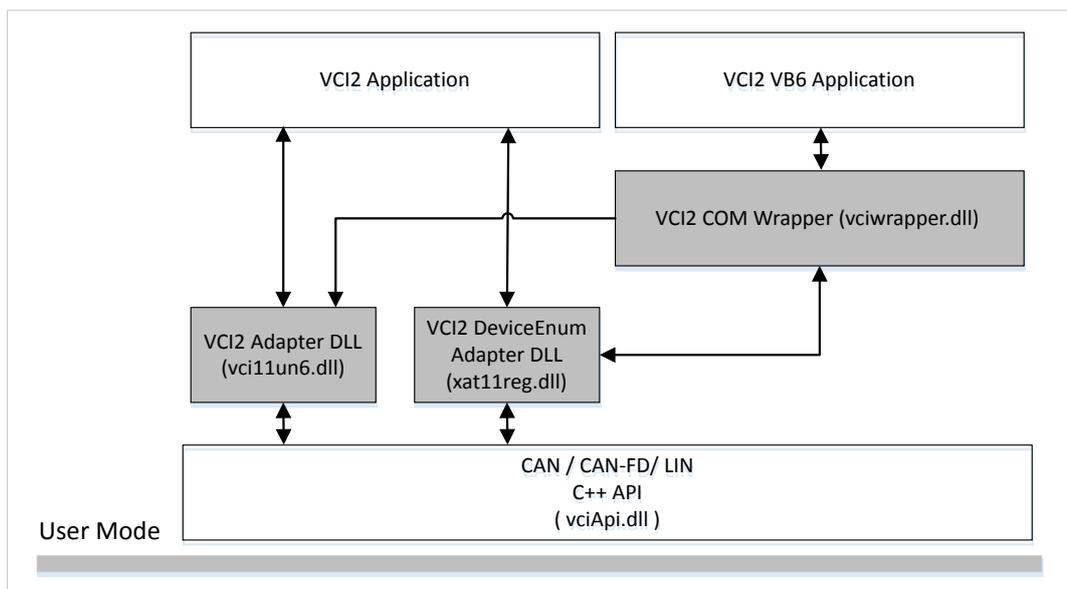

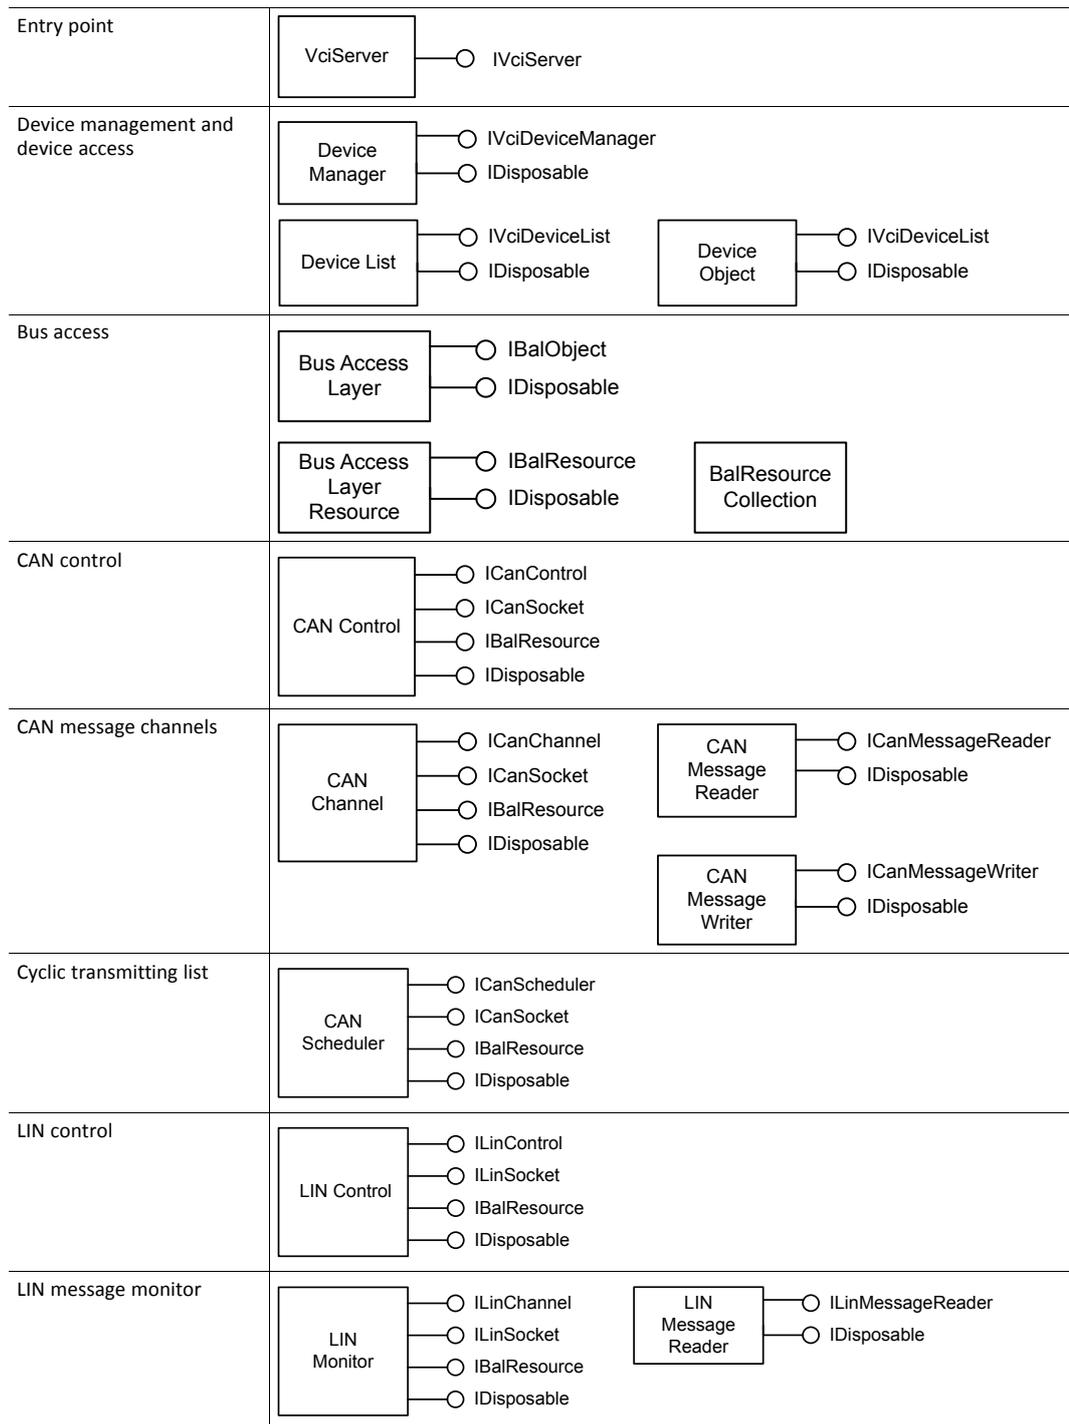

Fig. 4 VCI V2 adapter

### 2.3 Sub-Components and .NET Interfaces/Classes

### 2.4 Programming Examples

With installing the VCI driver, programming examples are automatically installed in `c:\Users\Public\Documents\HMS\Ixxat VCI 4.0\Samples\dotnet`.

## 3 Including the .NET API

### 3.1 Including Manually into Own Projects

- ▶ Add the dependencies to the project.  
*Ixxat.Vci4.Contact.dll* and the loader *Ixxat.Vci4.dll* are necessary.
- ▶ Copy the native components (*vcinet.x86.dll* and *vcinet.x64.dll*) to the bin directory.

### 3.2 Including into Own Projects via NuGet

The including via NuGet automates the steps that are necessary when including manually. Via NuGet the strongly named package *Ixxat.Vci4StrongName* and the package without assigned strong name *Ixxat.Vci4* are available.

- ▶ Install the package *Ixxat.Vci4StrongName* for the project.
- ▶ Observe further information in manuals (in package *Ixxat.Vci4.Manuals*) and on [www.nuget.org](http://www.nuget.org).

#### Using Older VisualStudio Versions (VS2012 and earlier)

A bug in older VisualStudio versions (VS2012 and earlier) sometimes drops the copy task during a build, which copies the native components to the bin directory (*vcinet.x86.dll* and *vcinet.x64.dll*).

- ▶ Use the batch build command as a workaround.
- ▶ If exceptions are thrown during the startup, check the exception text for hints and check if all required components are deployed to the output directory.

### 3.3 Porting the Applications

The VCI API.DLL of the VCI 4 is compatible to the VCI 3. When installing the VCI.NET API Version 4, Version 3 is also installed.

To port the applications of the VCI 3 .NET API to the current VCI 4 .NET adapter, the following sources are changed:

- using statements
- access to device manager
- use of CAN/LIN messages
- requesting the channel status

#### Using Statements

```
// Version3
using Ixxat.Vci3;
// Version4
using Ixxat.Vci4;
```

#### Access to Device Manager

```
// Version3
deviceManager = VciServer.GetDeviceManager();
// Version4
deviceManager = VciServer.Instance().DeviceManager;
```

### Use of CAN/LIN Messages (Transmit)

Because of the abstraction of messages via interfaces the use of a factory class is necessary:

```
// Version3
CanMessage canMsg = new CanMessage();
// Version4
IMessageFactory factory = VciServer.Instance().MsgFactory;
ICanMessage canMsg = (ICanMessage)factory.CreateMsg(typeof(ICanMessage));
```

### Use of CAN/LIN Messages (Receive)

Exclusively the declaration is affected.

```
// Version3
CanMessage canMessage;
// Version4
ICanMessage canMessage;
```

### Requesting the Channel Status

The change of the implementation of the LineStatus (to distinguish uninitialized statuses) eventually makes adaptations of the access to this objects necessary.

## 4 Device Management and Device Access

The device management provides listing of and access to devices logged into the VCI server.

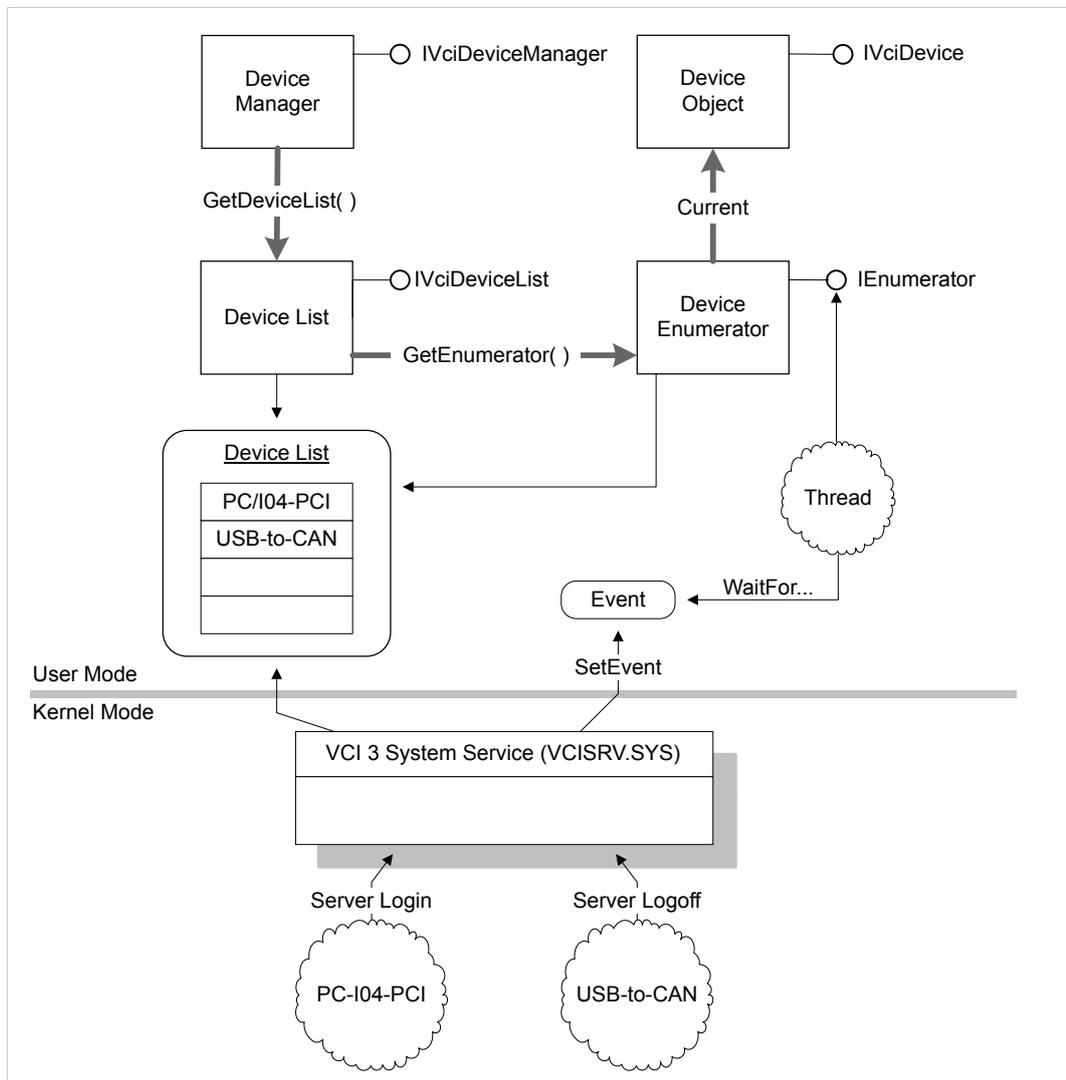

Fig. 5 Device management components

The VCI server manages all devices in a system-wide global device list. When the computer is booted or a connection between device and computer is established the device is automatically logged into the server. If a device is no longer available for example because the connection is interrupted, the device is automatically removed from the device list.

The logged in devices are accessed via the VCI device manager or its interface **IVciDeviceManager**. The property `VciServer.DeviceManager` returns a reference to this interface.

Main Device Information		
Interface	Type	Description
Description	String with description of the interface	For example USB-to-CAN compact
<i>VciObjectId</i>	Unique ID of device	When a device logs in, it is allocated a system-wide unique ID (VCIID). This ID is required for later access to the device.
<i>DeviceClass</i>	Device class	All device drivers identify their supported device class by a worldwide unique ID (GUID). Different devices belong to different device classes, for example the USB-to-CAN belongs to a different device class as PC-104/PCI.
<i>UniqueHardwareId</i>	Hardware ID	Each device has a unique hardware ID. The ID can be used to differentiate between two interfaces or to search for a device with a certain hardware ID. Remains after restart of the system. Because of that it can be stored in the configuration file and enables automatic configuration of the application after program and system start.
<i>DriverVersion</i>	Version number of driver	
<i>HardwareVersion</i>	Version number of interface	
<i>Equipment</i>	Technical equipment of interface	Included table of <i>VciCtrlInfo</i> structures provides information about number and type of bus connections present on the interface. Table entry 0 describes bus connection 1, table entry 1 the bus connection 2 etc.

## 4.1 Listing Available Devices

- ▶ To access the global device list, call the method `IVciDeviceManager.GetDeviceList`.
  - Returns pointer to the interface `IVciDeviceList` of the device list.

It is possible to monitor changes in the device list and to request enumerators for the device list. There are different possibilities to navigate in the device list.

### Requesting Enumerators

Method `IVciDeviceList.GetEnumerator` returns `IEnumerator` interface of a new enumerator object for the device list.

- ▶ Call the method `IEnumerator.Current`.
  - Returns a new device object with information of the interface with each call.
- ▶ To access the information of the property `Current` of the standard interface `IEnumerator`, convert the provided pure object reference to `IVciDevice` type.
- ▶ To increment the internal index, call the method `IEnumerator.MoveNext`.
  - `IEnumerator.Current` returns device object for the next interface.

The list is completely passed when the method `IEnumerator.MoveNext` returns the value `FALSE`.

### Reset the Internal List Index

- ▶ Call the method `IEnumerator.Reset`.
  - The following call of the method `IEnumerator.MoveNext` returns again information about the first device in the device list.

Devices that can be added or removed during operation, like for example USB devices are logged in with connecting and logged off with disconnecting. The devices are also logged in or off when the operation system activates or deactivates a device driver in the device manager.

### Monitoring Changes in the Device List

- ▶ Create an `AutoResetEvent` object or a `ManualResetEvent` object.
- ▶ Assign the object to the list with `IVciDeviceList.AssignEvent`.

*Use `AutoResetEvent` to set the event in signaled state, when a device logs in or off the VCI server after calling the method.*

---

## 4.2 Accessing Individual Devices

All `Ixxat` interfaces provide one or more components resp. access levels for various application areas. Here the Bus Access Layer (BAL) is relevant. The BAL allows the control of the controller and the communication with the fieldbus.

The different access levels of a `Ixxat` interface cannot be opened simultaneously. For example, if an application opens the BAL, the access level used by CANopen master API can only be opened again after the BAL is released or closed.

Certain access levels are additionally protected against multiple opening, for example two CANopen applications cannot use one `Ixxat` interface simultaneously.

The BAL can be opened by several programs simultaneously, to allow different applications the simultaneous access to different bus connections (further information see [Accessing the Bus Controller, p. 21](#)).

## 5 Communication Components

### 5.1 First In/First Out Memory (FIFO)

The VCI contains an implementation for First In/First Out memory objects.

#### FIFO Features

- Dual-port memory, in which data is written on the input side and read on the output side.
- Chronological sequence is preserved, i. e. data that is written in the FIFO at first is also read at first.
- Similar to the functionality of a pipe connection and therefore also named pipe.
- Used to transfer data from a transmitter to the parallel receiver. Agreement with a lock mechanism, that has access to the common memory area at a certain point of time is not necessary.
- No locking, possible to be overcrowded, if receiver does not manage to read the data in time.
- Transmitter writes the messages to transmit with writer interface in the FIFO. Receiver parallel reads data with reader interface.

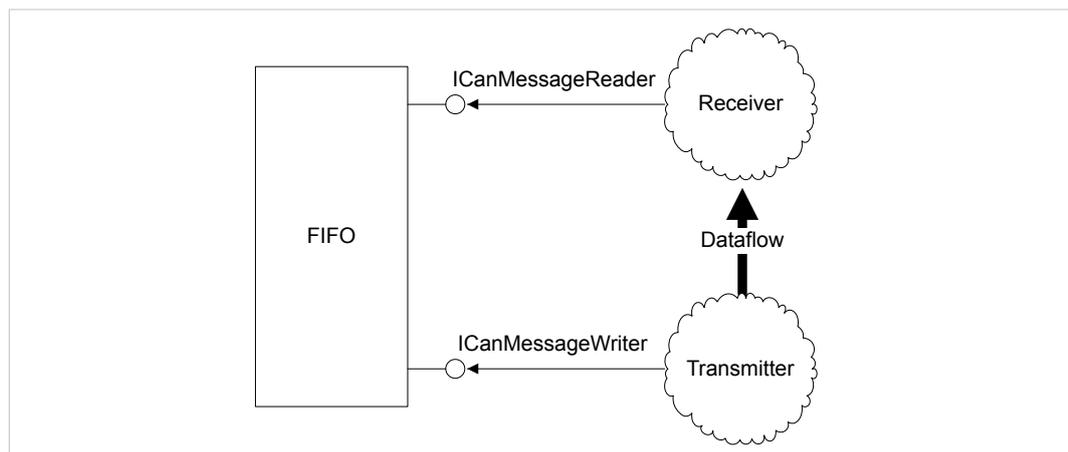

Fig. 6 FIFO data flow

#### Access

- Writing and reading access to a FIFO is possible simultaneously, a receiver is able to read data while a transmitter writes new data to the FIFO.
- Simultaneous access of several transmitters resp. receivers to the FIFO is not possible.
- Multiple access to interfaces `ICanMessageReader` and `ICanMessageWriter` is prevented, because the respective interface of the FIFO can only be opened once, i. e. not until the interface is released with `IDisposable.Dispose` it can be opened again.
- To prevent simultaneous access to one interface by different threads of an application:
  - ▶ Make sure, that the methods of an interface can only be called by one thread of the application (e. g. create a separate message channel for the second thread).
  - or
  - ▶ Synchronize the access to an interface with the respective thread: Call the method `Lock` before every access of the FIFO and the method `Unlock` of the respective interface after accessing.

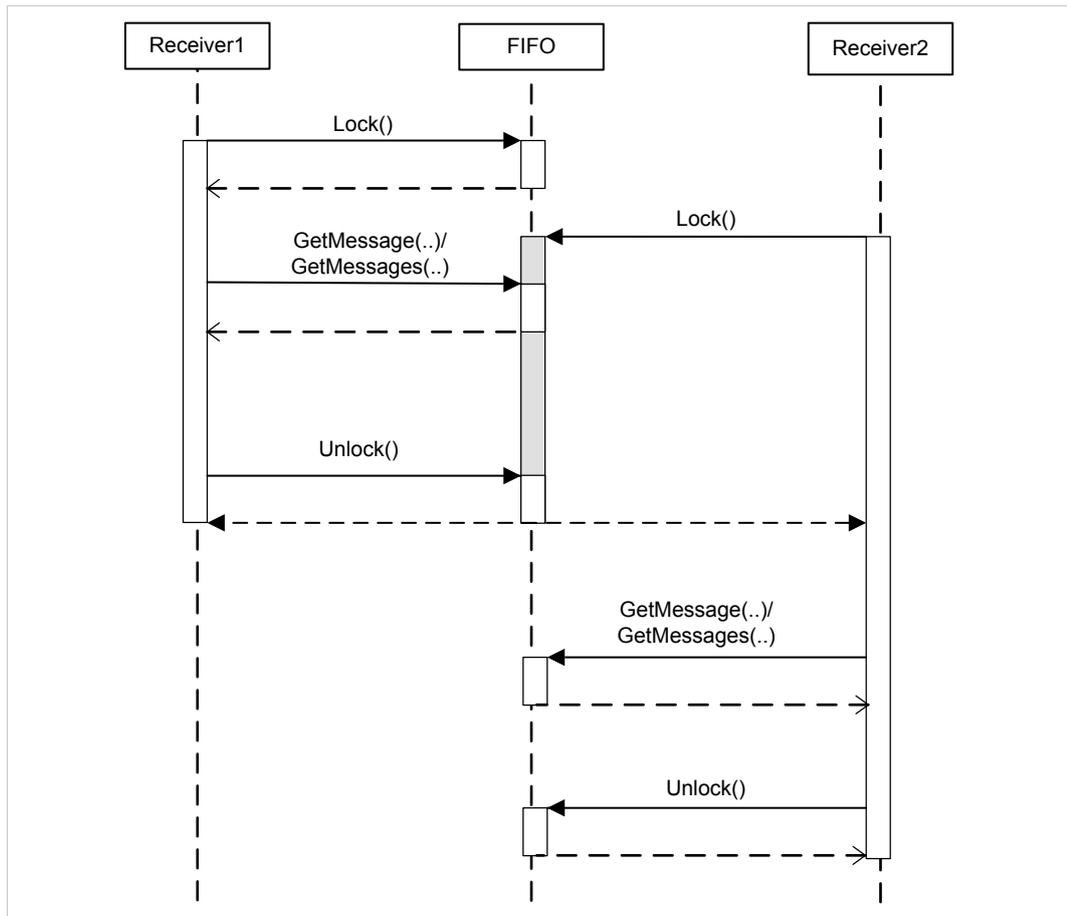

Fig. 7 FIFO locking mechanism

Receiver 1 calls method `Lock` and gains access to the FIFO. The following call of `Lock` by receiver 2 is blocked as long as receiver 1 releases the FIFO with calling method `Unlock`. Now receiver 2 can start processing. In the same way two transmitters that access the FIFO with the interface `ICanMessageWriter` can be synchronized.

The FIFOs provided by the VCI also allow the exchange of data between two processes, i. e. over the boundaries of the process.

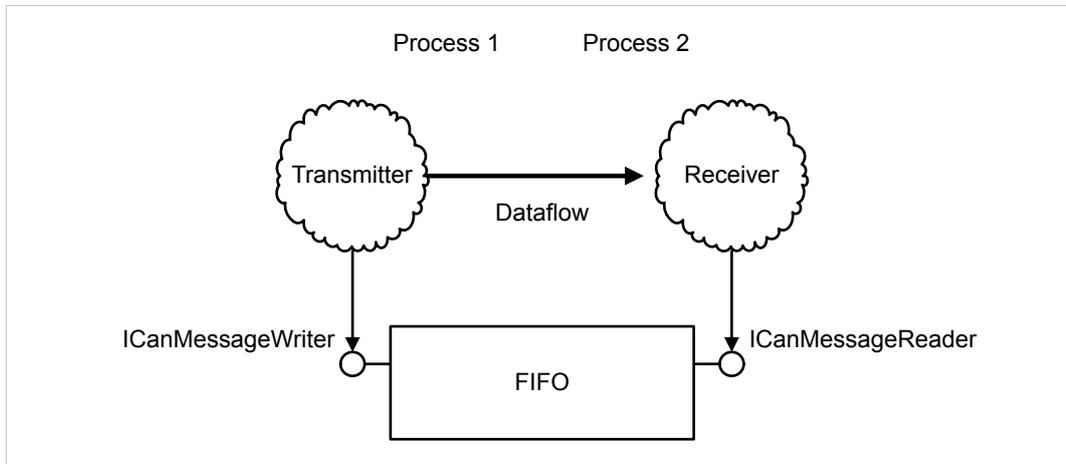

Fig. 8 FIFO for data exchange between two processes

FIFOs are also used to exchange data between components running in the kernel mode and programs running in the user mode.

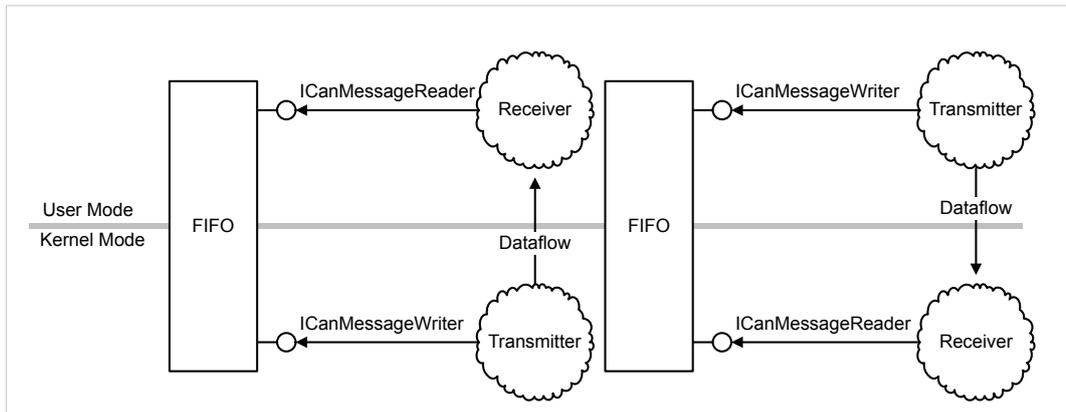

Fig. 9 Possible combination of a FIFO for data exchange between user and kernel mode

### 5.1.1 Functionality of the Receiving FIFO

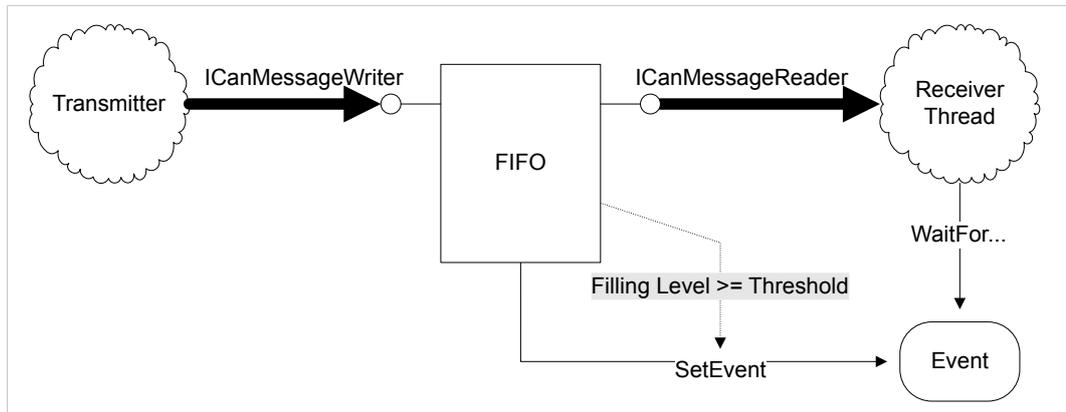

Fig. 10 Functionality Receiving FIFO

At the receiving side FIFOs are addressed via the interface `ICanMessageReader`.

Access files to read:

- ▶ To read individual messages, call the method `GetMessage`.
- or
- ▶ To read several messages, call the method `GetMessages`.
- ▶ To release one or more read and processed elements, call the method `IDisposable.Dispose`.

#### Event Object

It is possible to assign an event object to the FIFO to prevent that the receiver has to ask if new data is available for reading. The event object is set to a signaled status if a certain filling level is reached.

- ▶ Create `AutoResetEvent` or `ManualResetEvent`.
  - Returned handle is assigned to the FIFO with method `AssignEvent`.
- ▶ Set the threshold resp. filling level that triggers the event with property `Threshold`.

Afterwards the application is able to wait for the event and to read the received data with one of the methods `WaitOne` or `WaitAll`.

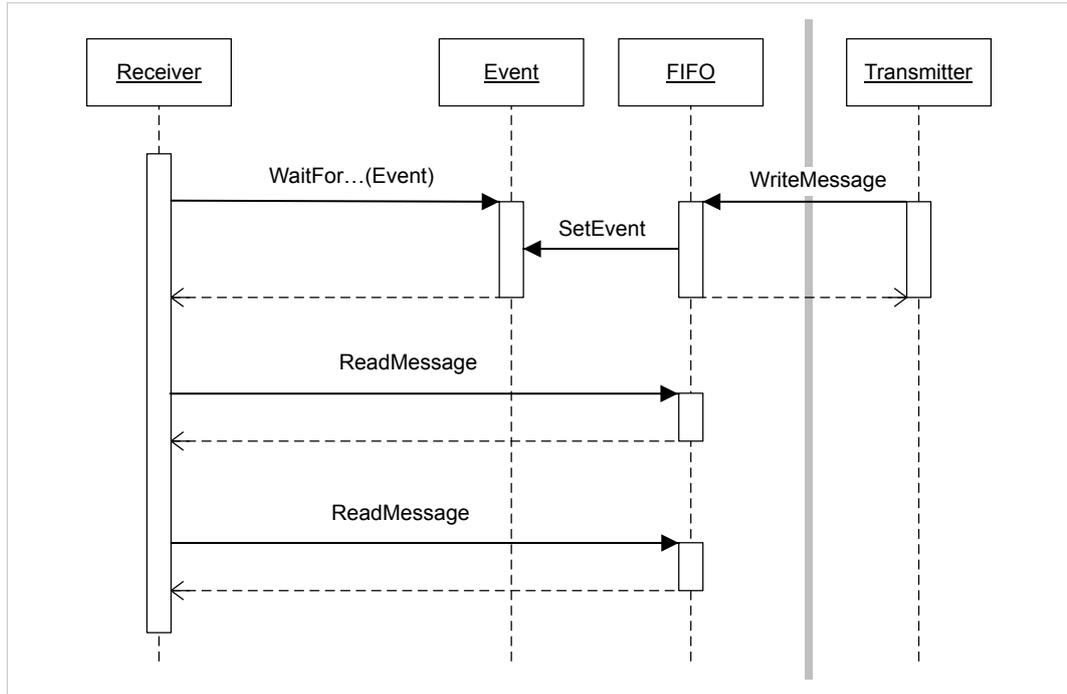

Fig. 11 Receiving sequence event-driven reading of data from the FIFO

Since the event is exclusively triggered with the exceedance of the set threshold, make sure that all entries of the FIFO are read in case of event-driven reading. If the threshold is set for example 1 and already 10 elements are in the FIFO when the event happens and only one is read, a following event will not be triggered until the next write-access. If no further write-access follows by the transmitter 9 unread elements are in the FIFO that are not shown as event anymore.

### 5.1.2 Functionality of the Transmitting FIFO

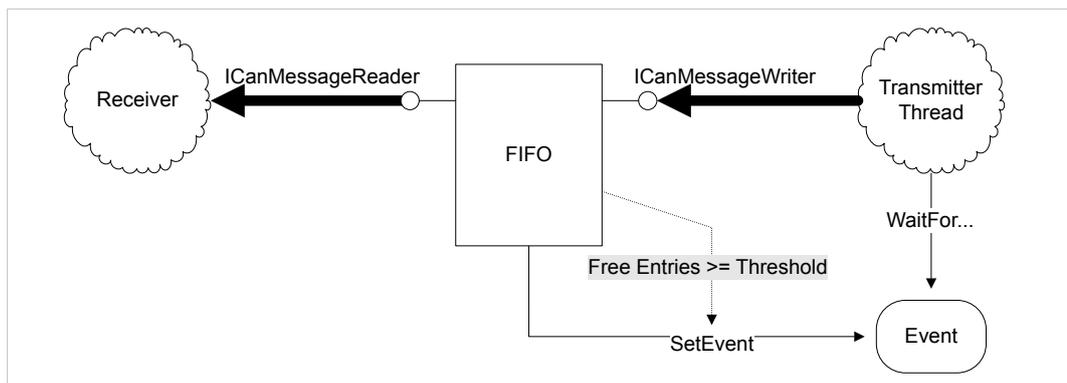

Fig. 12 Functionality transmitting FIFO

At the transmitting side FIFOs are addressed via the interface `ICanMessageWriter`.

Write the data to be transmitted in the FIFO:

- ▶ To write individual messages to the FIFO, call the method `WriteMessage`.
- or
- ▶ To write several messages to the FIFO, call the method `WriteMessages`.

### Event Object

It is possible to assign an event object to the FIFO to prevent that the receiver has to check if free elements are available. The event object is set to a signaled status if the number of free elements exceeds a certain value.

- ▶ Create `AutoResetEvent` or `ManualResetEvent`.
  - Returned handle is assigned to the FIFO with the method `AssignEvent`.
- ▶ Set the threshold resp. the number of free elements that trigger the event with property `Threshold`.

Afterwards the application is able to wait for the event and to write new data in the FIFO with one of the methods `WaitOne` or `WaitAll`.

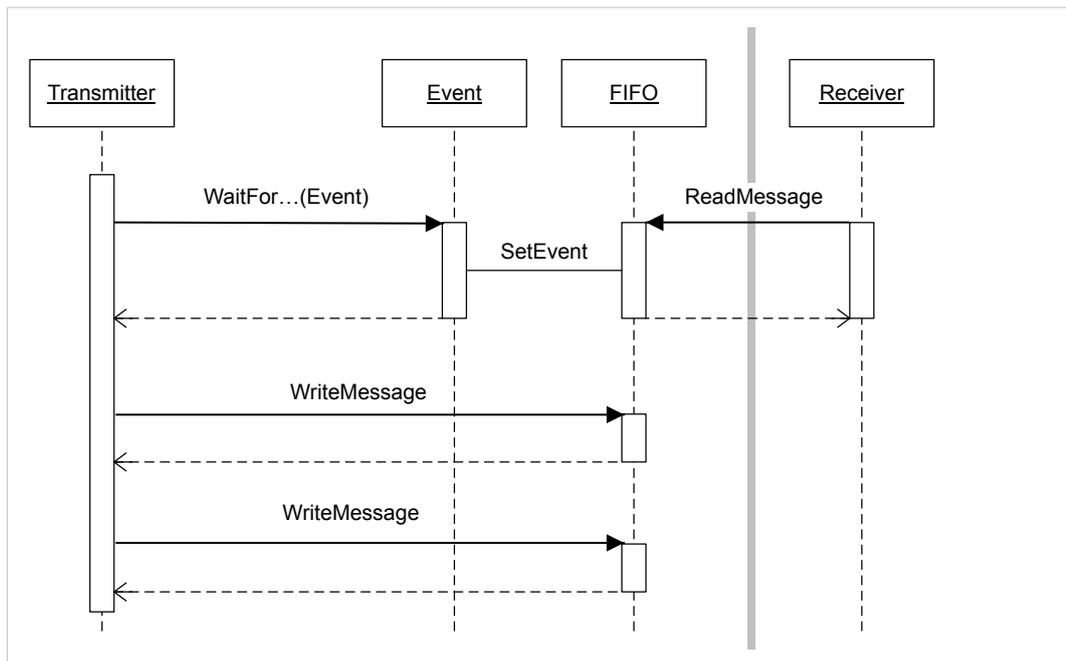

Fig. 13 Transmitting sequence event-driven writing of data to FIFO

## 6 Accessing the Bus Controller

Via the Bus Access Layer (BAL) the fieldbusses connected to the CAN interface are accessed.

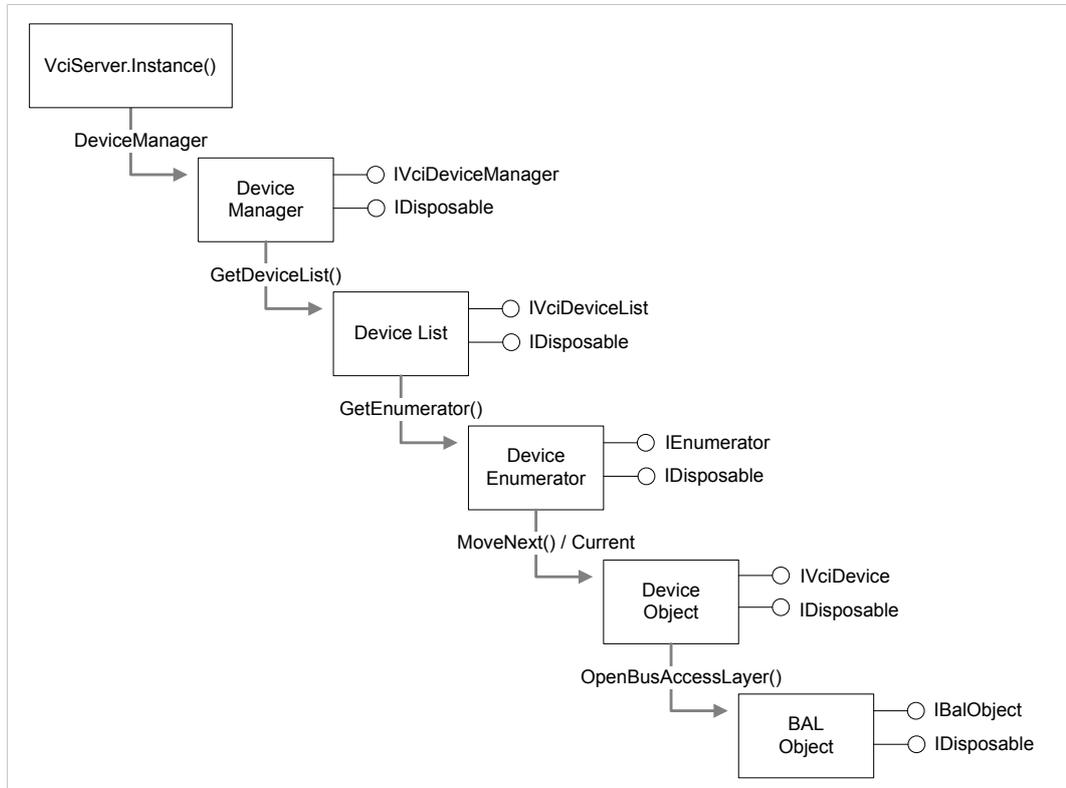

Fig. 14 Components for accessing the bus

- ▶ Search the adapter in the device list and open the BAL with `IVciDeviceManager.OpenBusAccessLayer`.
- ▶ After opening release the references to the device manager, device list, device enumerator or device object that are no longer needed with `IDisposable.Dispose`.

For further work with the adapter only the BAL object resp. its interface `IBalObject` is necessary. The BAL of an interface can be opened simultaneously by several programs.

The BAL object supports several types of bus connections.

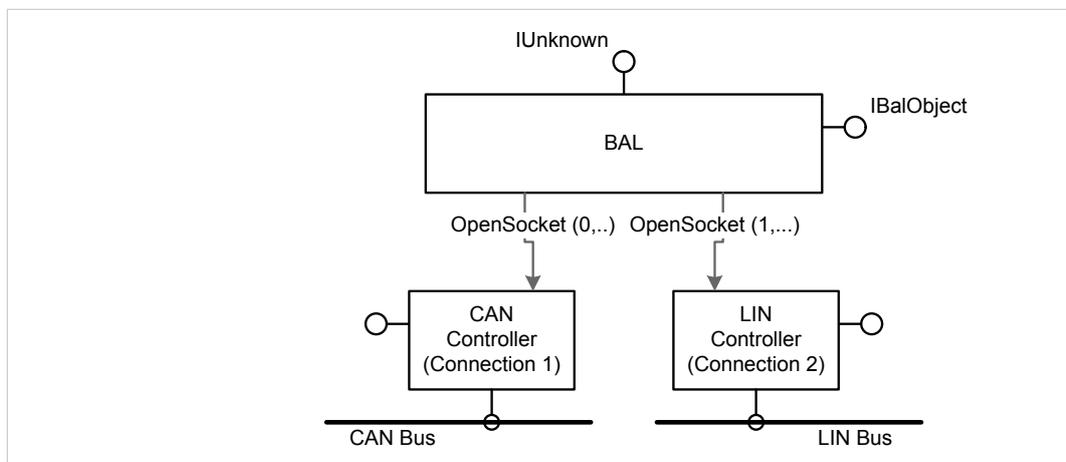

Fig. 15 BAL with CAN and LIN controller

### Determine Number and Type of Provided Connections

- ▶ Call the property `IBalObject.Resources`.
  - Returns information in form of a `BalResourceCollection`, that contains a BAL resource object for every provided bus connection.
  - The BAL returns the version number of the device firmware via the property `IBalObject.FirmwareVersion`.

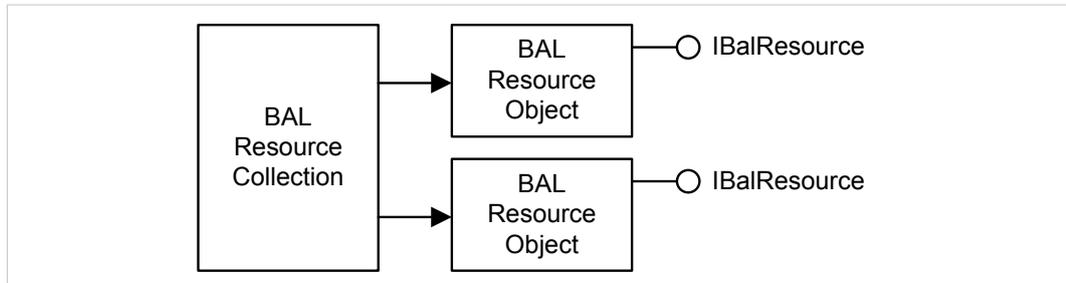

Fig. 16 `BalResourceCollection` with two bus connections

### Accessing the Connection or the Interface of the Connection

Access connections with the method `IBalObject.OpenSocket`.

- ▶ In the first parameter specify the number of the connection to be opened. The value has to be in the range 0 to `IBalObject.Resources.Count-1`. To open connection 1 enter value 0, for connection 2 value 1 etc.
- ▶ In the second parameter specify the ID of the interface to access the connection.
- ▶ Call method.
  - Returns reference to the requested interface.
  - Possibilities resp. interfaces of a connection are dependent on the supported bus.

*Certain interfaces of a controller can only be accessed by one program, others can be accessed by any number of programs simultaneously. The rules of accessing the particular interfaces are dependent on the type of the connection and are described in detail in the following chapters.*

## 6.1 CAN Controller

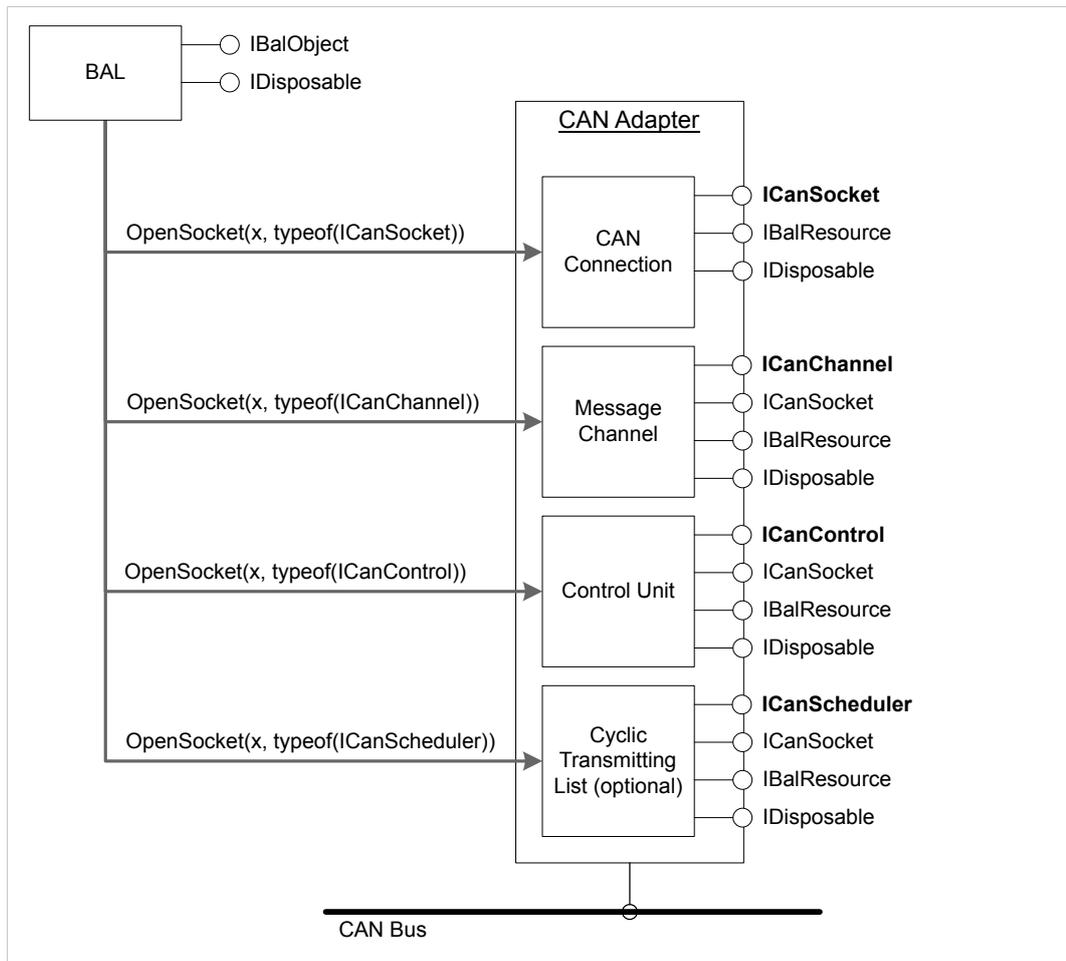

Fig. 17 Components CAN controller

Access to individual components of the CAN controller via the following interfaces:

- ICanSocket, ICanSocket2 (CAN controller), see [Socket Interface, p. 24](#)
- ICanControl, ICanControl2 (control unit), see [Control Unit, p. 31](#)
- ICanChannel, ICanChannel2 (message channels), see [Message Channels, p. 24](#)
- ICanScheduler, ICanScheduler2 (cyclic transmitting list), see [Cyclic Transmitting List, p. 39](#), optional, exclusively with devices with their own microprocessor

The extended interfaces ICanSocket2, ICanControl2, ICanChannel2 and ICanScheduler2 allow the access to the new functions of CAN FD controllers. With standard controllers they can be used for further filter possibilities

### 6.1.1 Socket Interface

The socket interface `ICanSocket` resp. `ICanSocket2` is used to request features, possibilities and the operating status of the CAN controller. The interface is not subjected to any access restrictions and can be opened by multiple applications simultaneously. Controlling via this interface is not possible.

Open with method `IBalObject.OpenSocket`.

- ▶ In parameter `socketType` enter the type `ICanSocket` or `ICanSocket2`.
- ▶ Call the method.

The properties of the CAN controller, like for example the supported features are provided via properties.

- ▶ To determine the current operating status of the controller, call the property `LineStatus`.

### 6.1.2 Message Channels

Message channels consist of a receiving and an optional transmitting FIFO. One or more message channels are possible per CAN controller. CAN messages are exclusively received and transmitted via message channels.

Message channels with extended functionality (CAN FD) contain an additional, optional input filter.

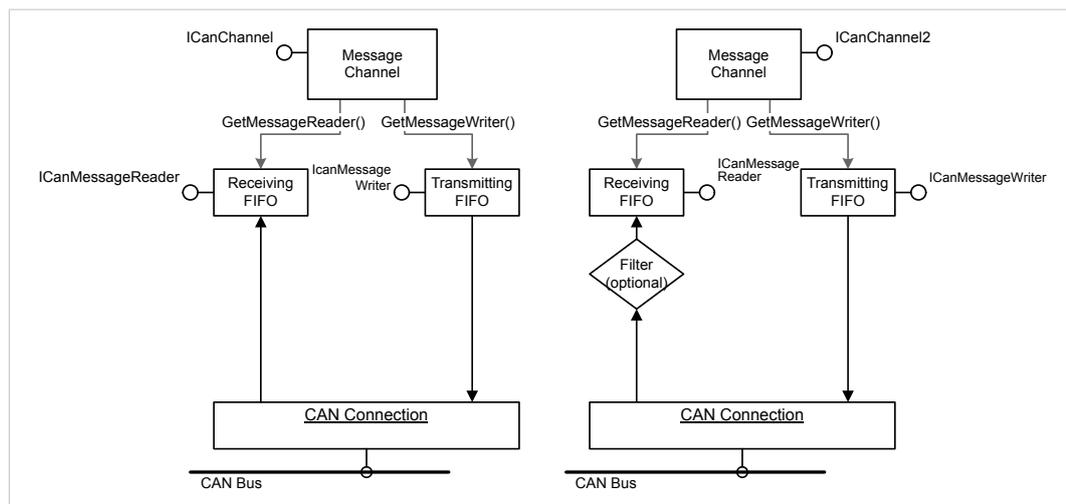

Fig. 18 Components and interfaces of a message channel

All CAN connections support message channels of the type `ICanChannel` and `ICanChannel2`. If the extended functionality of a message channel of type `ICanChannel2` is usable, is depending on the CAN controller of the connection. If the connection provides for example only a standard CAN controller, the extended functionality can not be used. With a message channel of type `ICanChannel` the extended functionality of a CAN FD can neither be used.

The basic functionality of a message channel is the same, irrespective whether the connection is used exclusively or not. In case of exclusive use the message channel is directly connected to the CAN controller.

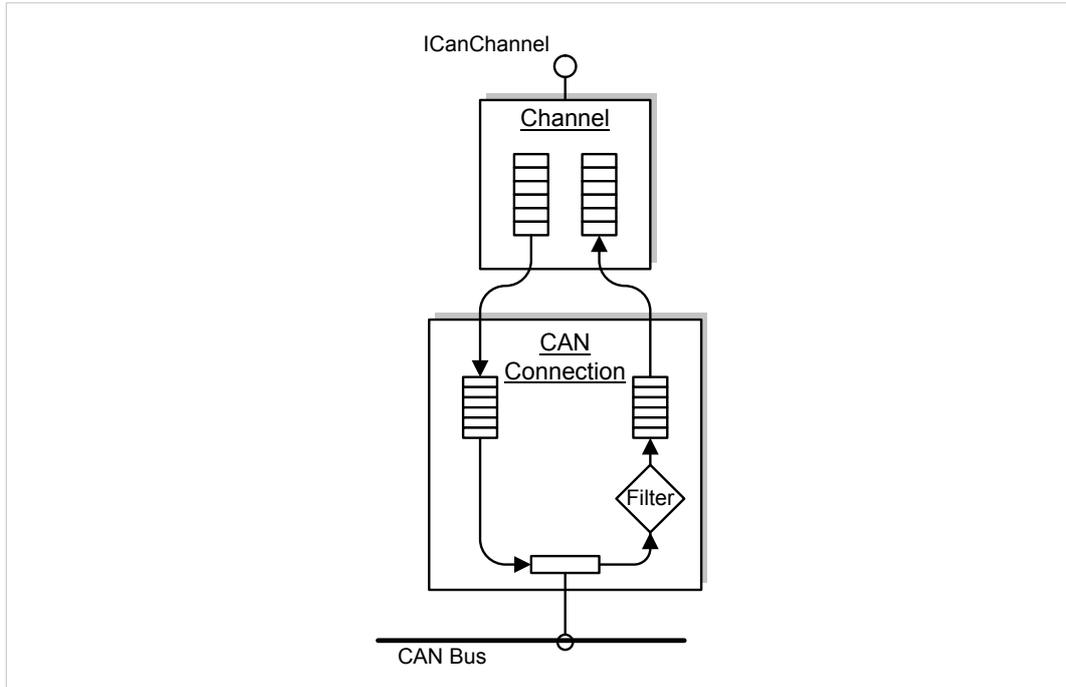

Fig. 19 Exclusive use of a message channel

In case of non-exclusive use the individual message channels are connected to the controller via a distributor.

The distributor transfers all received messages to all active channels and parallel the transmitted messages to the controller. No channel is prioritized i. e. the algorithm used by the distributor is designed to treat all channels as equal as possible.

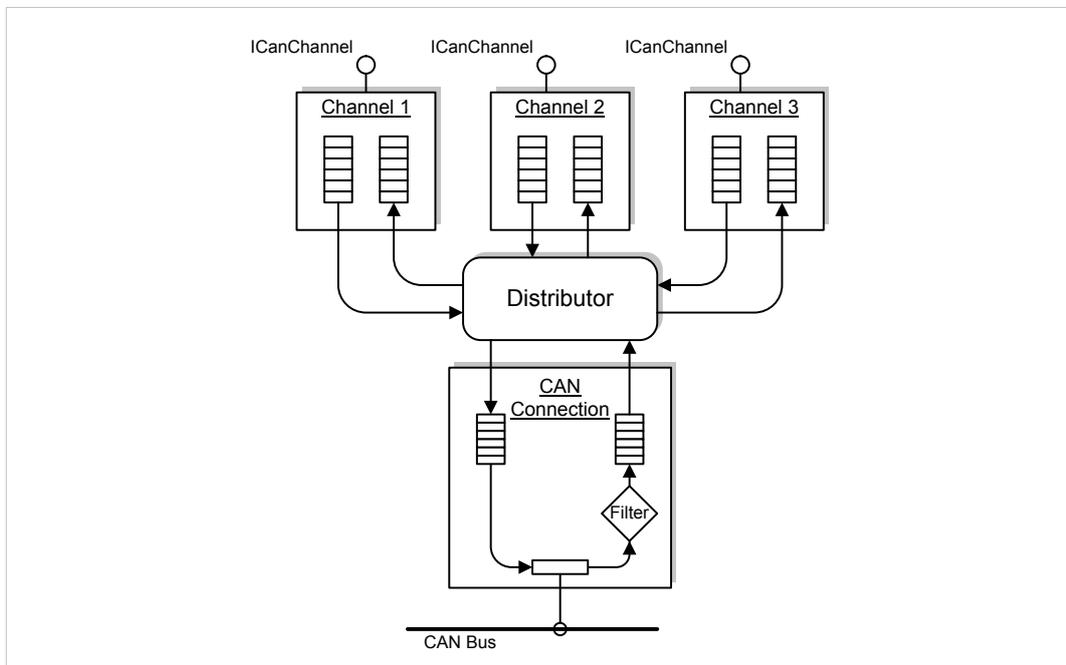

Fig. 20 CAN message distributor: possible configuration with three channels

### Creating a Message Channel

Create with the method `IBalObject.OpenSocket` resp. for channels with extended functionality with `IBalObject2.OpenSocket`.

- ▶ In parameter `socketType` enter the type `ICanChannel`.

The random access memory required for the FIFOs limits the possible number of channels.

### Initializing the Message Channel

A newly generated message channel contains neither a receiving nor a transmitting FIFO. Before first use initialization is necessary.

Initialize and create receiving and transmitting FIFOs with the method `ICanChannel.Initialize` resp. with channels with extended functionality with `ICanChannel2.Initialize`.

- ▶ In the parameters specify the size of each FIFO in number of CAN messages.
- ▶ To use the controller exclusively (after successful execution no further message channels can be used), enter the value `TRUE` in parameter `exclusive`.

or

To use the controller non-exclusively (further message channels can be opened and controller can be used by other applications), enter the value `FALSE` in parameter `exclusive`.

- ▶ Call the method.

In case of the use of message channels with extended functionality an additional optional receiving filter can be created.

- ▶ In case of a 29 bit ID filter, specify the size of the filter table in number of IDs in parameter `filterSize`.  
In case of a 11 bit ID filter the size of the filter table is set to 2048 and cannot be changed.
- ▶ If no receiving filter is needed, set `filterSize` to 0.
- ▶ Specify the functionality of the 11 bit and 29 bit ID filter in parameter `filterMode`.
- ▶ Call the method.

*Initially specified functionality can be changed later for both filters separately with the method `SetFilterMode` at inactive message channels.*

---

### Activating the Message Channel

A new message channel is inactive. Messages can only be transmitted and received, if the message channel is active and the CAN controller is started.

- ▶ Activate the message channel with the method `ICanChannel.Activate`.
- ▶ Deactivate the message channel with the method `ICanChannel.Deactivate`.

### Receiving CAN messages

The messages received on the bus and accepted by the filter are written to the receiving FIFO.

- ▶ Request the interface `ICanMessageReader` that is required to read with `ICanChannel.GetMessageReader` resp. with channels with extended functionality with `ICanChannel2.GetMessageReader`.

Reading messages from the FIFO:

- ▶ Call the method `ReadMessage`.  
or
- ▶ To read several messages with one method call (optimized for high data throughput), create a field of CAN messages.
- ▶ Assign the field to the method `ReadMessages`.
  - `ReadMessages` tries to fill the field with received data.
  - Number of actually read messages is indicated with response value.

### Possible Use of `ReadMessage`

```
void DoMessages( ICanMessageReader reader )
{
    ICanMessage message;
    while( reader.ReadMessage(out message) )
    {
        // Processing of message
    }
}
```

### Possible Use of `ReadMessages`

```
void DoMessages( ICanMessageReader reader )
{
    ICanMessage[] messages;

    int readCount = reader.ReadMessages(out messages);
    for( int idx = 0; idx < readCount; idx++ )
    {
        // Processing of message
    }
}
```

### Reception Time of a Message

The reception time of a message is available via the interface `ICanMessage resp. ICanMessage2` in the property `TimeStamp`. The property contains the number of timer ticks that elapsed since the start of the timer. Dependent on the hardware the timer either starts with the start of the controller or with the start of the hardware. The time stamp of the `CanMsgFrameType.Info` message, that is written to the receiving FIFOs of all active message channels when the control unit is started, contains the starting point of the controller.

To get the relative reception time of a message (in relation to the start of the controller) subtract the starting point of the controller from the absolute reception time of the message.

After an overrun of the counter the timer is reset.

### Calculation of the relative reception time ( $T_{rx}$ ) in ticks:

- $T_{rx} = \text{TimeStamp of message} - \text{TimeStamp of CanMsgFrameType.Info (start of controller)}$

Property `TimeStamp` available via the interface `ICanMessage resp. ICanMessage2`

### Calculation of the length of a tick resp. the resolution of a time stamp in seconds: ( $t_{tsc}$ ):

- $t_{tsc} [s] = \text{TimeStampCounterDivisor} / \text{ClockFrequency}$

Fields `TimeStampCounterDivisor` and `ClockFrequency`, see properties `ICanSocket.ClockFrequency` and `ICanSocket.TimeStampCounterDivisor`

- channels with extended functionality:

$t_{tsc} [s] = \text{TimeStampCounterDivisor} / \text{ClockFrequency}$

Fields `TimeStampCounterDivisor` and `ClockFrequency`, see properties `ICanSocket2.ClockFrequency` and `ICanSocket2.TimeStampCounterDivisor`

### Calculation of the reception time ( $T_{rx}$ ) in seconds:

- $T_{rx} [s] = \text{TimeStamp} * t_{tsc}$

### Transmitting CAN Messages

Messages are transmitted via the transmitting FIFO of the message channel.

- ▶ Request the interface `ICanMessageWriter` that is required for transmitting with the method `ICanChannel.GetMessageWriter resp. with channels with extended functionality with ICanChannel2.GetMessageWriter`.
- ▶ Transmit messages with the method `SendMessage`.
- ▶ Assign the message of the type `CanMessage` to be transmitted in the parameter `message`.
- ▶ To transmit a message delayed, enter a value unequal 0 in parameter `TimeStamp` (further information see [Transmitting Messages Delayed, p. 29](#)).

Exclusively messages of the type `CanMsgFrameType.Data` can be transmitted. Other message types are ignored by the controller and automatically rejected.

### Possible Use of `SendMessage`

```
bool SendMessage( ICanMessageWriter writer, UInt32 id, Byte data )
{
    IMessageFactory factory = VciServer.Instance().MsgFactory;
    ICanMessage canMsg = (ICanMessage)factory.CreateMsg( typeof( ICanMessage ) );

    // Initialize CAN message.
```

```
message.TimeStamp          = 0; // No delayed transmitting
message.Identifier         = id; // Message ID (CAN ID)
message.FrameType          = CanMsgFrameType.Data;
message.SelfReceptionRequest = false; // No Self Reception
message.ExtendedFrameFormat = false; // Standard frame
message.DataLength         = 1; // only 1 data byte
message[0]                 = data;

// transmit message
return writer.SendMessage(message);
}
```

### Transmitting Messages Delayed

A controller with set bit `ICanSocket.SupportsDelayedTransmission` supports the possibility to transmit messages delayed, with a latency between two consecutive messages.

Delayed transmission can be used to reduce the message load on the bus. This prevents that other to the bus connected participants receive too much data in too short a time, which can cause data loss in slow nodes.

- ▶ In field `CanMessage.TimeStamp` specify the time in ticks that have to pass at a minimum before the next message is passed to the controller.

### Delay Time

- Value 0 triggers no delay, that means a message is transmitted the next possible time.
- The maximal possible delay time is specified by the field `ICanSocket.MaxDelayedTXTicks`.
- Resolution of a tick in seconds is calculated with the values of the fields `ICanSocket.ClockFrequency` and `ICanSocket.DelayedTXTimeDivisor` resp. `ICanSocket2.DelayedTXTimerClockFrequency` and `ICanSocket2.DelayedTXTimerDivisor`.

### Calculation of the Resolution of a Tick in Seconds

- Resolution [s] = `DelayedTXTimeDivisor / ClockFrequency`

The specified delay time represents a minimal value as it can not be guaranteed that the message is transmitted exactly after the specified time. Also, it has to be considered that if several message channels are used simultaneously on one connection the specified value is basically exceeded because the distributor handles all channels one after another.

### Recommendation:

- ▶ If an application requires a precise time sequence, use the connection exclusively.

### Transmitting Messages Uniquely

Transmitting messages with set `SingleShotMode` flag the controller tries to transmit only once. If this transmitting attempt is not successful the message is rejected and there is no automatic transmitting repetition.

This happens for example if one or more bus participants are transmitting simultaneously. If the participant that is transmitting a message with set `SingleShotMode` flag bit loses the bus assignment (arbitration), the message is rejected and further transmitting is not attempted.

The functionality is exclusively available if the property `ICanSocket2.SupportsSingleShotMessages` returns `TRUE`.

### Transmitting Messages with High Priority

Transmitting messages with set `HighPriorityMsg` flag are registered by the controller in a controller specific transmitting buffer that takes precedence over messages in the standard transmitting buffer and primarily transmits.

The functionality is exclusively available if the property `ICanSocket2.SupportsHighPriorityMessages` returns `TRUE`. If the bit is used observe that messages that are already in the transmitting FIFO can not be overtaken. The functionality is of minor impact resp. can only be sensibly used if the controller is opened exclusively and the transmitting FIFO is empty before addressing a message with set flag `HighPriorityMsg`.

### 6.1.3 Control Unit

The control unit provides the following functions via the interface `ICanControl`:

- configuration of CAN controller
- configuration of the transmitting features of the CAN controller
- configuration of CAN message filters
- requesting of current operating state

To make sure, to stop several applications for example from trying to start and stop the CAN controller simultaneously, the control unit can exclusively be opened by one application.

#### Opening the Interface

Open with the method `IBalObject.OpenSocket`.

- ▶ Specify the type `ICanControl` resp. with channels with extended functionality `ICanControl2` in parameter `socketType`.
  - If the method returns *Exception*, the component is already used by another program.
- ▶ Close the opened control unit with the method `IDisposable.Dispose` and release access by other applications.

If other interfaces are opened during the closing of the control unit, the current settings remain.

#### Controller States

The control unit resp. the CAN controller is always in one of the following states:

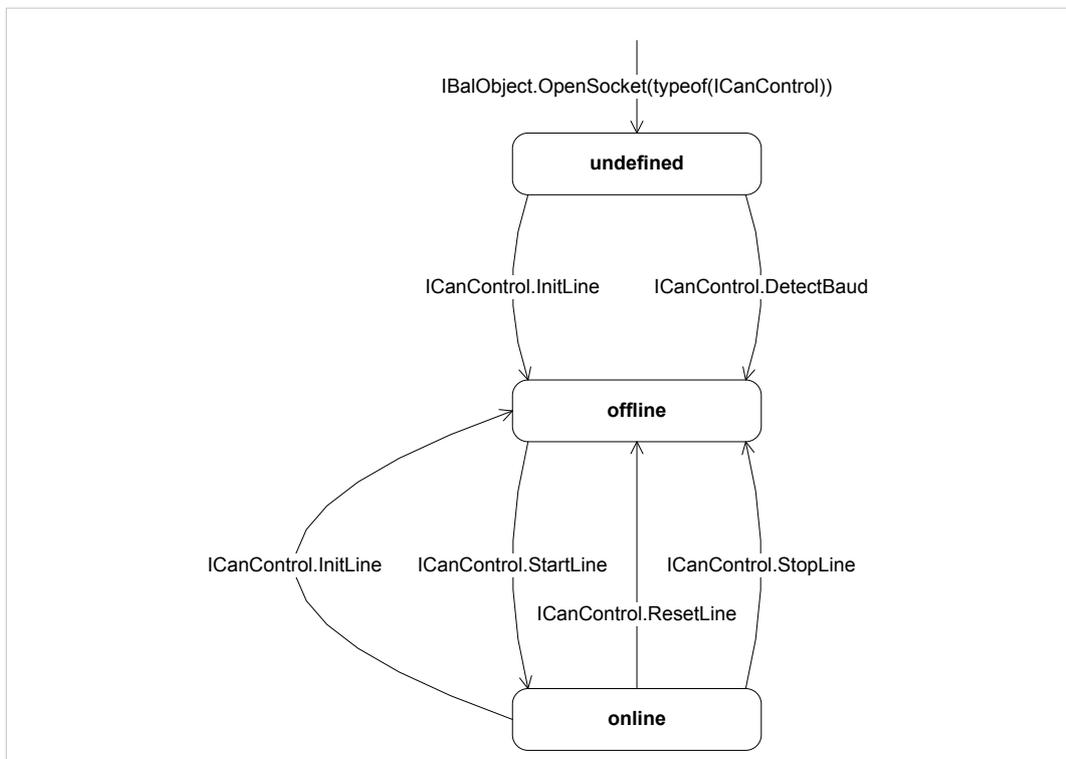

Fig. 21 Controller states

### Initializing the Controller

After the first opening of the control unit via the interface `ICanControl` or `ICanControl2` the controller is in an undefined state.

- ▶ To leave an undefined state, call the method `InitLine` or `DetectBaud`.
  - Controller is in state *offline*.
- ▶ Specify the operating mode and bit rate of the controller with the method `InitLine`.
- ▶ Specify the operating mode in field *operatingMode*.
- ▶ Specify the bitrate in `bitrate` (see [Specifying the Bit Rate, p. 33](#)).
- ▶ Call the method.
  - Controller is initialized with the specified values.

### Starting the Controller

To start the CAN controller and data transmission between controller and bus:

- ▶ Make sure that the CAN controller is initialized (see [Initializing the Controller, p. 32](#)).
- ▶ Call the method `StartLine`.
  - Control unit is in state *online*.
  - Incoming messages are forwarded to all opened and active message channels.
  - Transmitting messages are transferred to the bus.

After successful start of the controller the control unit transmits an information message to all active message channels. The property `FrameType` of this message contains the value `CanMsgFrameType.Info`, the first data byte `Data[0]` the value `CanMsgInfoValue.Start` and the property `TimeStamp` the relative starting point (normally 0).

### Stopping (resp. Reset) the Controller

- ▶ Call the method `StopLine`.
  - Controller is in state *offline*.
  - Data transfer between controller and bus is stopped.
  - Controller is deactivated.
  - Specified acceptance filter and filter list remain.
  - In case of an ongoing data transfer of the controller the function waits until the message is transmitted completely over the bus, before the message transmission is stopped. No faulty telegram is on the bus.

or

- ▶ Call the method `ResetLine`.
  - Controller is in state *offline*.
  - Controller hardware is reset.
  - Message filters are deleted.

After calling the method `ResetLine` a faulty message telegram on the bus is possible, if a not completely transferred message is in the transmitting buffer of the controller, because the transmitting is canceled also during an ongoing data transfer.

If `StopLine` or `ResetLine` are called the control unit transmits an information message to all active channels. The property `FrameType` of the message contains the value `CanMsgFrameType.Info`, the first data byte `Data[0]` the value `CanMsgInfoValue.Stop` resp. `CanMsgInfoValue.Reset` and the property `TimeStamp` the value 0. Neither `ResetLine` nor `StopLine` delete the content of the receiving and transmitting FIFOs of a message channel.

### Specifying the Bit Rate

- Specify with the fields `CanBitrate.Btr0` and `CanBitrate.Btr1`.

The values of the fields `CanBitrate.Btr0` and `CanBitrate.Btr1` correspond to the values of the bus timing register BTR0 and BTR1 of Philips SJA1000 CAN controller with a clock frequency of 16 MHz.

Bus Timing Values with CiA resp. CANopen Conform Bit Rates			
Bit rate (KBit)	Predefined CiA bit rates	BTR0	BTR1
10	<code>CanBitrate.Cia10KBit</code>	0x31	0x1C
20	<code>CanBitrate.Cia20KBit</code>	0x18	0x1C
50	<code>CanBitrate.Cia50KBit</code>	0x09	0x1C
125	<code>CanBitrate.Cia125KBit</code>	0x03	0x1C
250	<code>CanBitrate.Cia250KBit</code>	0x01	0x1C
500	<code>CanBitrate.Cia500KBit</code>	0x00	0x1C
800	<code>CanBitrate.Cia800KBit</code>	0x00	0x16
1000	<code>CanBitrate.Cia1000KBit</code>	0x00	0x14
100	<code>CanBitrate._100KBit</code>	0x04	0x1C

### Determine the Bit Rate Used in the Network

If the CAN connector is connected to a running network with unknown bit rate the current bit rate can be determined.

Method `DetectBaud` requires a field with predefined bus timing values.

- Call the method `DetectBaud`.
- Determined bus timing values can be assigned to `InitLine`.

### Example for Use of Method for Automatic Initialization of a CAN Controller in a CANopen System

```
void AutoInitLine( ICanControl control )
{
    // Determine bit rate
    int index = control.DetectBaud(10000, CanBitrate.CiaBitRates);

    if (-1 < index)
    {
        CanOperatingModes mode;
        mode = CanOperatingModes.Standard | CanOperatingModes.ErrFrame;
        control.InitLine(mode, CanBitrate.CiaBitRates[index]);
    }
}
```

### 6.1.4 Message Filter

All control units and message channels with extended functionality have a two-level message filter. The data messages are exclusively filtered by the ID (CAN ID). Data bytes are not considered.

Transmitting messages with set *Self reception request* bit are entered to the receiving buffer as soon as they are transmitted over the bus. The message filter is bypassed.

#### Operating Modes

Message filters can be ran in different operation modes:

- **Blocking mode** (`CanFilterModes.Lock`):  
Filter blocks all data messages, independent of the ID. Used for example if an application is only interested in information, error or status messages.
- **Passing mode** (`CanFilterModes.Pass`):  
Filter is completely opened and all data messages can pass. Default operation mode in case of using the interface `ICanChannel`.
- **Inclusive filtering** (`CanFilterModes.Inclusive`):  
All data messages with either in the acceptance filter released ID or registered in the filter list ID can pass the filter (e. i. all registered IDs). Default operation mode in case of using the interface `ICanControl`.
- **Exclusive filtering** (`CanFilterModes.Exclusive`):  
All data messages with either in the acceptance filter released ID or registered in the filter list ID are blocked by the filter (e. i. all registered IDs).

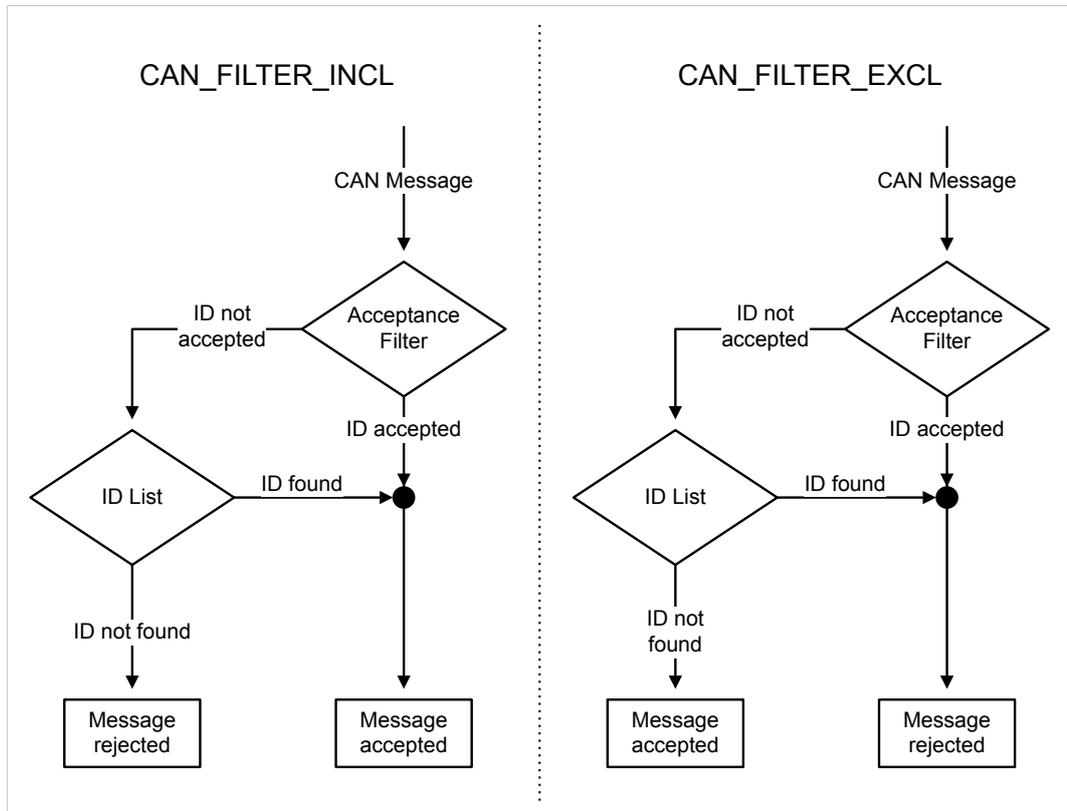

In case that the interface `ICanControl` is used, the operating mode of the filter cannot be changed and is preset to `CanFilterModes.Inclusive`. In case that the interface `ICanControl2` resp. `ICanChannel2` is used, the operation mode can be set to one of the above stated modes with the method `SetFilterMode`.

To ask for the operating mode of the filter call method `GetFilterMode`.

---

**Inclusive and Exclusive Operating Mode**

**Fig. 22 Filtering mechanism inclusive and exclusive operating mode**

The first filter level consists of an acceptance filter that compares the ID of a received message with a binary bit model. If the ID correlates with the set bit model the ID is accepted. In case of inclusive operating mode the message is accepted. In case of exclusive operating mode the message is immediately rejected.

If the first filter level does not accept the ID it is forwarded to the second filter level. The second filter level consists of a list with registered message IDs. If the ID of the received message is equal to an ID in the list, the message is accepted in case of inclusive filtering and rejected in case of exclusive filtering.

**Filter Chain**

Each message channel is connected to a controller either directly or indirectly via a distributor (see *Message Channels, p. 24*). If a filter is used both with the controller and with the message channel a multi-level filter chain is formed. Messages that are filtered out by the controller are invisible for the down-streamed channels.

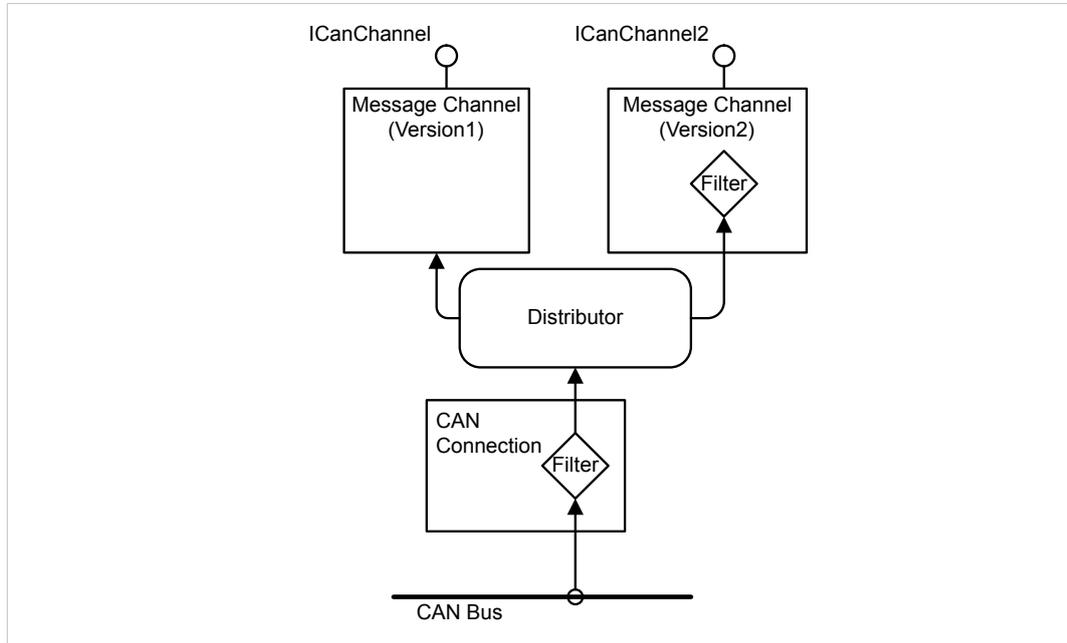

Fig. 23 Filter chain

### Setting the Filter

Control units and message channels have separated and independent filters for 11 bit and 29 bit IDs. Messages with 11 bit ID are filtered by the 11 bit filter and messages with 29 bit ID by the 29 bit ID filter.

To distinguish between 11 and 29 bit ID filter all stated methods have the parameter *bSelect*.

---

 *Changes of the filters during operation are not possible.*

---

 *If the controller is reset or initialized, all filters are specified to let all messages pass.*

---

- ▶ Make sure that the control unit is *offline* resp. that the message channel is inactive.

If the interfaces `ICanControl2` resp. `ICanChannel2` are used, the operating mode of the filter is preset during the initialization of the component. The specified value serves simultaneously as default value for the method `ICanControl2.ResetLine`.

- ▶ Make sure, that the controller is in state *offline*.
- ▶ To set the filter after initialization, call the method `SetFilterMode`.
- ▶ Specify the filter with methods `SetAccFilter`, `AddFilterIds` and `RemFilterIds`.
- ▶ In parameter *bSelect* select 11 or 29 bit filter.

The bit samples in parameters *code* and *mask* determine which IDs can pass the filter.

- ▶ In parameter *code* and *mask* specify two bit samples.
  - Value of *code* specifies the bit model of the ID.
  - *mask* specifies which bit is used for the comparison.

If a bit in *mask* has the value 0, the correlating bit in *code* is not used for the comparison. But if it has the value 1, it is relevant for the comparison.

In case of the 11 bit filter exclusively the lower 12 bits are used. In case of the 29 bit filter the bits 0 to 29 are used. All other bits of the 32 bit value must be set to 0 before one of the methods is called.

Correlation between the bits in the parameters *code* and *mask* and the bits in the message ID:

11 Bit ID Filter												
Bit	11	10	9	8	7	6	5	4	3	2	1	0
	ID10	ID9	ID8	ID7	ID6	ID5	ID4	ID3	ID2	ID1	ID0	RTR

29 Bit ID Filter												
Bit	29	28	27	26	25	...	5	4	3	2	1	0
	ID28	ID27	ID26	ID25	ID24	...	ID4	ID3	ID2	ID1	ID0	RTR

The bits 1 to 11 resp. 1 to 29 correspond to the bits 0 to 10 resp. 0 to 28. Bit 0 of every value defines the value of the remote transmission request bit (RTR) of a message.

The following example shows the values that must be used for *code* and *mask* to register message IDs in the range of 100 h to 103 h (of which also the RTR bit must be 0) in the filter:

<i>code</i>	001 0000 0000 0
<i>mask</i>	111 1111 1100 1
Valid IDs:	001 0000 00xx 0
ID 100h, RTR = 0:	001 0000 0000 0
ID 101h, RTR = 0:	001 0000 0001 0
ID 102h, RTR = 0:	001 0000 0010 0
ID 103h, RTR = 0:	001 0000 0011 0

The example shows that with a simple acceptance filter only individual IDs or groups of IDs can be released. If the desired identifier do not correspond with a certain bit model a second filter level, a list with IDs, must be used. The amount of IDs a list can receive can be configured. Every list has space for up to 2048 IDs resp. 4096 entries.

- ▶ Register individual IDs or groups of IDs with the method `AddFilterIds`.
- ▶ If necessary, remove from the list with the method `RemFilterIds`.

The parameters *code* and *mask* have the same format as showed above.

If method `AddFilterIds` is called with same values as in the above example, the method enters the identifier 100 h to 103 h to the list.

- ▶ To register exclusively an individual ID in the list, specify the desired ID (including RTR bit) in *code* and in *mask* the value `FFFh` (11 bit ID) resp. `3FFFFFFFh` (29 bit ID).
- ▶ To disable the acceptance filter completely, when calling the method `SetAccFilter` enter in *code* the value `CanAccCode.None` and in *mask* the value `CanAccMask.None`.
  - Filtering is exclusively done with ID list.
  - or
- ▶ Configure the acceptance filter with the values `CanAccCode.All` and `CanAccMask.All`.
  - Acceptance filter accepts all IDs and ID list is ineffective.

### 6.1.5 Cyclic Transmitting List

With the optionally provided transmitting list of the controller up to 16 messages can be transmitted cyclically. The access to this list is limited to one application and therefore can not be used by several programs simultaneously. It is possible to increment a certain part of a CAN message after each transmitting process.

Open interface with method `IBalObject.OpenSocket`.

- ▶ In parameter `socketType` specify the type `ICanScheduler`.
  - If the method returns an error code respective `VciException`, the transmitting list is already under control of another program and can not be opened again.
  - If the method returns an error code respective `NotImplementedException`, the CAN controller does not support a cyclic transmitting list.
- ▶ If another transmitting list is opened, close the opened transmitting list with the method `IDisposable.Dispose`.
- ▶ Add message objects with `ICanScheduler.AddMessage` resp. in case of controller with extended functionality with `ICanScheduler2.AddMessage` to the list.
  - If run successfully the method returns a new cyclic transmitting object with the interface `ICanCyclicTXMsg`.

One controller exclusively supports one transmitting list. The methods of the interfaces `ICanScheduler` or `ICanScheduler2` therefore refer to the same list. As the interfaces are exclusively different regarding the data type of the transmitted messages, whereas the functionality is identical, only the functionality of the interface `ICanScheduler` is described hereafter.

- ▶ Specify the cycle time of a message in number of ticks in field `CanCyclicTXMsg.CycleTicks`.
- ▶ Make sure that the specified value is higher than 0 but less than or equal the value in field `ICanSocket.MaxCyclicMsgTicks`.
- ▶ Calculate the length of a tick resp. the cycle time ( $t_z$ ) of the transmitting list with the values in fields `ICanSocket.ClockFrequency` and `ICanSocket.CyclicMessageTimeDivisor` with the following formula:

$$t_z [s] = (\text{CyclicMessageTimeDivisor} / \text{ClockFrequency})$$

The transmitting task of the cyclic transmitting list divides the available time in individual segments resp. time frames. The length of a time frame is exactly the same as the length of a tick resp. the cycle time.

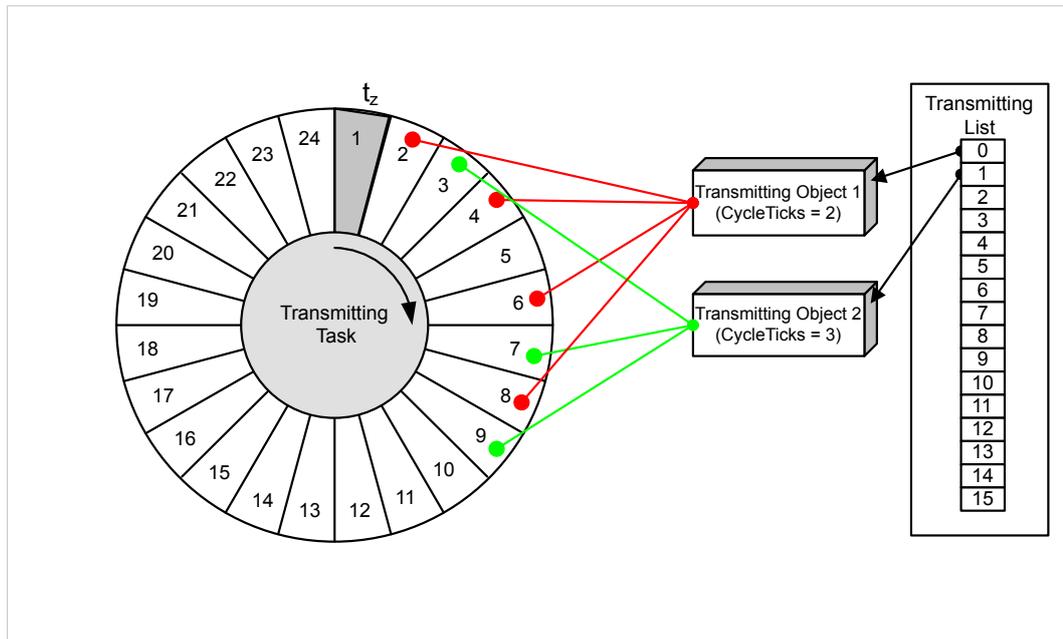

Fig. 24 Transmitting task of the cyclic transmitting list with 24 time frames

The number of time frames supported by the transmitting task is equal to the value in field *ICanSocket.MaxCyclicMsgTicks*.

The transmitting task can transmit exclusively one message per tick, e. i. exclusively one transmitting object can be matched to a time frame. If the transmitting object is created with a cycle time of 1 all time frames are occupied and no other objects can be created. The more transmitting objects are created, the larger their cycle time must be selected. The rule is: The total of all  $1/CycleTime$  must be less than 1.

In the example a message shall be transmitted every 2 ticks and a further message every 3 ticks, this amounts  $1/2 + 1/3 = 5/6 = 0.833$  and therefore a valid value.

When creating the transmitting object 1 the time frames 2, 4, 6, 8, etc. are occupied. If the second transmitting object is created with a cycle time of 3, it leads to a collision in the time frames 6, 12, 18, etc. because these time frames are already occupied by the transmitting object 1.

Collisions are resolved in shifting the new transmitting object in the respectively next free time frame. The transmitting object 2 of the example above then occupies the time frames 3, 7, 9, 13, 19, etc. The cycle time of the second object therefore is not met exactly and in this case leads to an inaccuracy of +1 tick.

The temporal accuracy of the transmitting of the objects is heavily depending on the message load on the bus. With increasing load the transmitting time gets more and more imprecise. The general rule is that the accuracy decreases with increasing bus load, smaller cycle times and increasing number of transmitting objects.

The field *CanCyclicTXMsg.AutoIncrementMode* specifies if certain parts of the message are automatically incremented after transmitting or if they remain unmodified.

If the value *CanCyclicTXIncMode.NoInc* is specified, the content of the message remains unmodified. With the value *CanCyclicTXIncMode.IncId* the field *Identifier* of the message is automatically incremented by 1 after every transmission. If the field *Identifier* reaches the value 2048 (11 bit ID) resp. 536.870.912 (29 bit ID) an overflow to 0 automatically takes place.

With the values `CanCyclicTXIncMode.Inc8` resp. `CanCyclicTXIncMode.Inc16` in field `CanCyclicTXMsg.AutoIncrementMode` an individual 8 bit resp. 16 bit value is incremented in the data field of the message after every transmission. The field `AutoIncrementIndex` specifies the index of the data field.

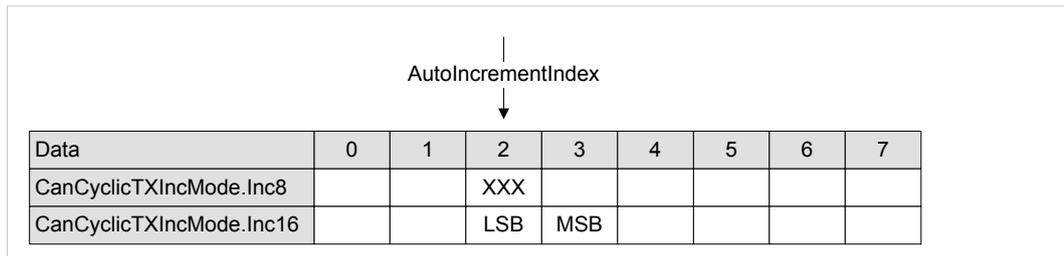

Fig. 25 Auto increment of data fields

Regarding 16 bit values, the low byte (LSB) is located in field `Data[AutoIncrementIndex]` and the high byte (MSB) in field `Data[AutoIncrementIndex + 1]`. If the value 255 (8 bit) resp. 65535 (16 bit) is reached, an overflow to 0 takes place.

- ▶ If necessary, remove the transmitting object from the list with the method `RemoveMessage`. The method expects the list index of the object to remove returned by `AddMessage`.
- ▶ To transmit the newly created transmitting object, call the method `SendMessage`.
- ▶ If necessary, stop transmitting with the method `StopMessage`.

The current status of an individual transmitting object is returned by the property `Status`. The transmitting object statuses are updated via method `UpdateStatus`.

The transmitting task is deactivated after opening the transmitting list. The transmitting task does not transmit any message in deactivated state, even if the list is created and contains started transmitting objects.

- ▶ To start all transmitting objects simultaneously, start all transmitting objects with the method `SendMessage`.
- ▶ To activate or deactivate the transmitting task, call the method `Resume`.
- ▶ To stop all transmitting objects simultaneously, call the method `Suspend`.
- ▶ To reset a transmitting task, call the method `Reset`.
  - Transmitting task is stopped.
  - All unregistered transmitting objects are removed from the specified cyclic transmitting list.

## 6.2 LIN-Controller

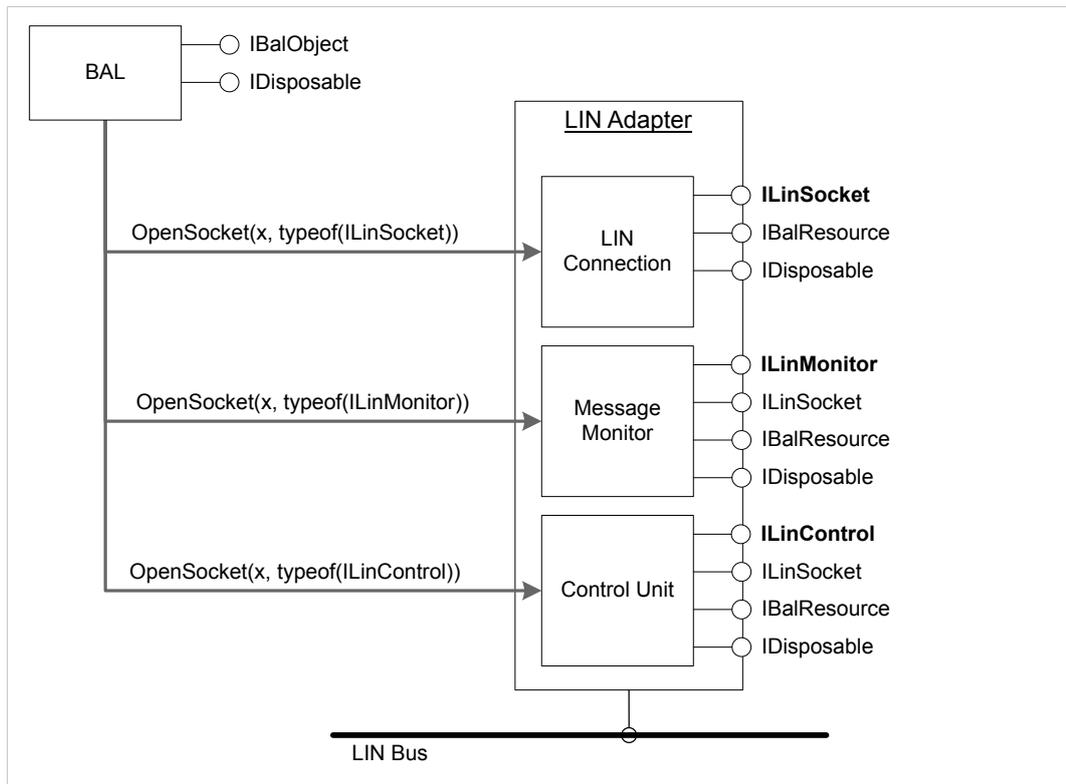

Fig. 26 Components LIN controller

Access to individual sub-components via interfaces `ILinSocket`, `ILinMonitor` and `ILinControl`.

`ILinSocket` (see [Socket Interface, p. 43](#)) provides the following functions:

- requesting of LIN controller functionality
- requesting of current controller state

`ILinMonitor` (see [Message Monitors, p. 43](#)):

- represents message monitor
- one or more message monitors possible per LIN connection
- LIN messages are exclusively received via message monitors.

`ILinControl` (see [Control Unit, p. 46](#)) provides the following functions:

- configuration of LIN controller
- configuration of transmitting features
- requesting of current controller state

### 6.2.1 Socket Interface

The interface `ILinSocket` is not subjected to any access restrictions and can be opened by multiple applications simultaneously. Controlling the connection via this interface is not possible.

Open with method `IBalObject.OpenSocket`.

- ▶ In parameter `socketType` specify the type `ILinSocket`.

The properties of the LIN controller, like for example supported functions are provided via properties.

- ▶ To determine the current operating mode and status of the controller, call the property `LineStatus`.

### 6.2.2 Message Monitors

A LIN message monitor consists of a receiving FIFO.

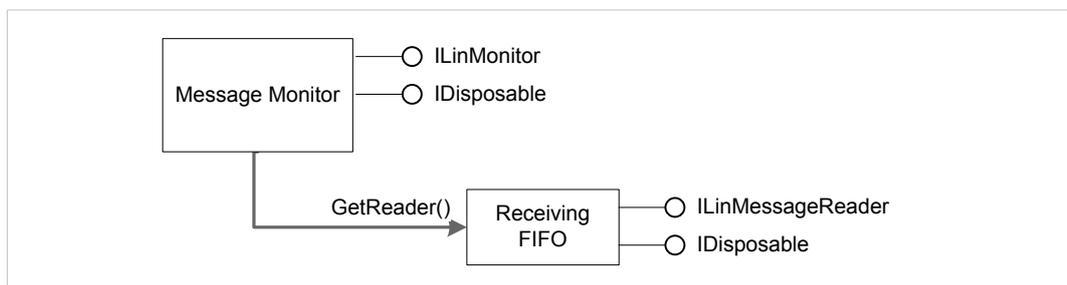

Fig. 27 Components LIN message monitor

The functionality of a message monitor is the same, irrespective whether the connection is used exclusively or not.

In case of exclusive use the message monitor is directly connected to the LIN controller.

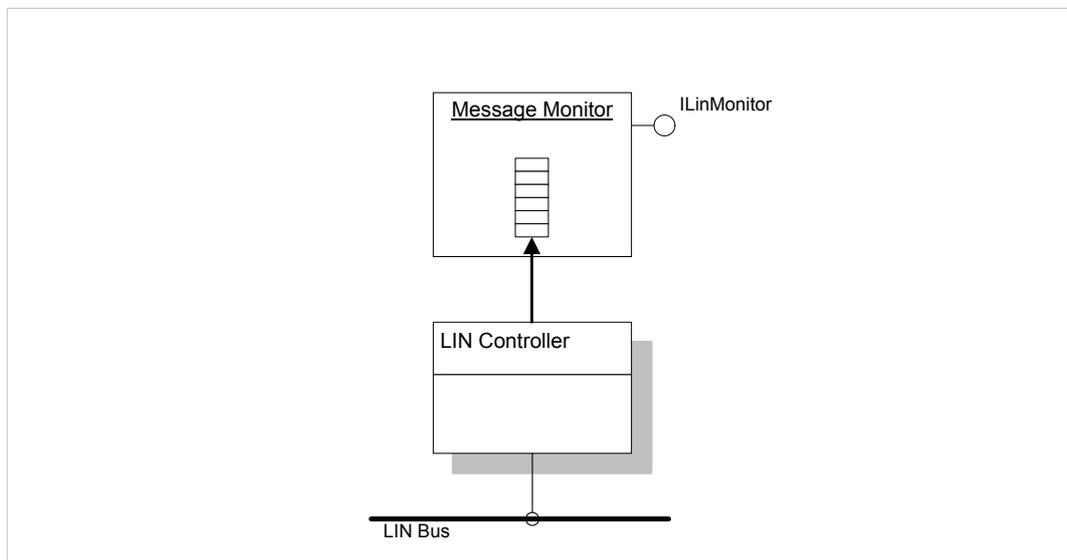

Fig. 28 Exclusive use

In case of non-exclusive use the individual message monitors are connected to the LIN controller via a distributor. The distributor transfers all on the LIN controller received messages to all active monitors. No monitor is prioritized i. e. the algorithm used by the distributor is designed to treat all monitors as equal as possible.

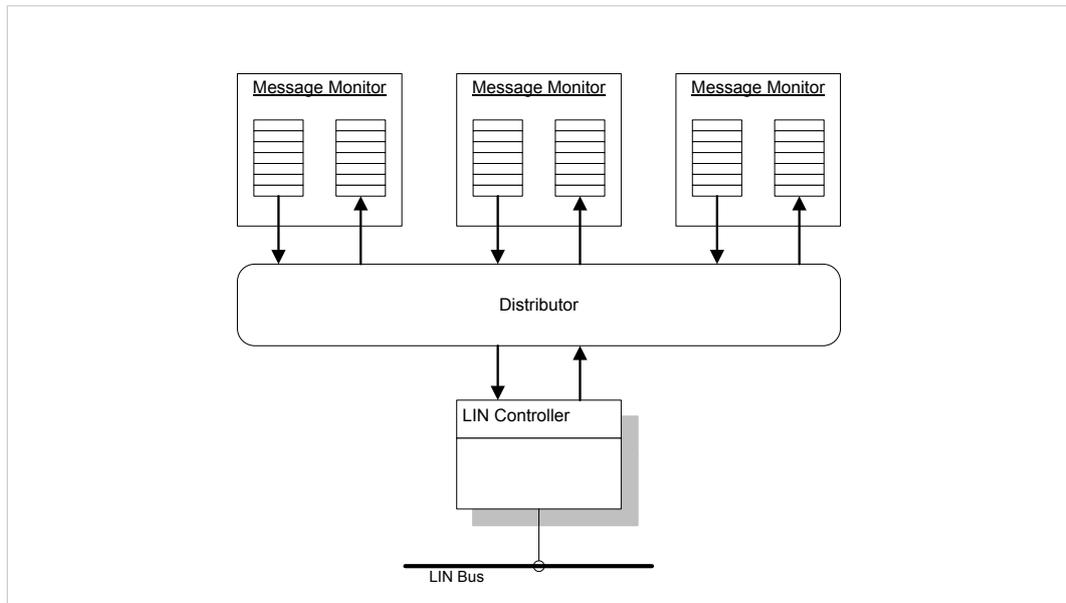

Fig. 29 Non-exclusive use (with distributor)

### Creating a Message Monitor

Create a message monitor with method `IBalObject.OpenSocket`.

- ▶ In parameter `socketType` specify the type `ILinMonitor`.
- ▶ To use the controller exclusively (after successful execution no further message monitors can be used) specify the value `TRUE` in parameter `exclusive`.

or

To use the controller non-exclusively (creation of any number of monitors is possible) specify the value `FALSE` in parameter `exclusive`.

### Initializing the Message Monitor

A newly generated message monitor contains no receiving FIFO.

- ▶ Initialize the message monitor and create the receiving FIFO with the method `ILinMonitor.Initialize`.
- ▶ In parameters specify the size of the receiving FIFO in number of LIN messages.

### Activating the Message Monitor

A newly generated monitor is deactivated. Messages are exclusively received by the bus if the message monitor is active and if the LIN controller is started. Further information about LIN controllers see chapter [Control Unit, p. 46](#).

- ▶ Activate the message monitor with the method `ILinMonitor.Activate`.
- ▶ Disconnect the active monitor with the method `ILinMonitor.Deactivate`.

### Receiving LIN Messages

- ▶ Request the interface `ILinMessageReader` that is necessary for reading with the method `ILinMonitor.GetMessageReader`.

Reading messages from the FIFO:

- ▶ Call the method `ReadMessage`.  
or
- ▶ To read several messages with one method call (optimized for high data throughput), create a field of LIN messages.
- ▶ Transmit the field to the method `ReadMessages`.
  - `ReadMessages` tries to fill the field with received data.
  - Number of actually read messages is indicated with response value.

### Possible Use of `ReadMessage`

```
void DoMessages( ILinMessageReader reader )
{
    ILinMessage message;
    while( reader.ReadMessage(out message) )
    {
        // Processing of message
    }
}
```

### Possible Use of `ReadMessages`

```
void DoMessages( ILinMessageReader reader )
{
    ILinMessage[] messages;

    int readCount = reader.ReadMessages(out messages);
    for( int idx = 0; idx < readCount; idx++ )
    {
        // Processing of message
    }
}
```

### 6.2.3 Control Unit

The control unit can exclusively be opened by one application. Simultaneous multiple opening of the Interface by several programs is not possible.

#### Opening the Interface

Open with the method `IBalObject.OpenSocket`.

- ▶ In parameter *socketType* specify the type `ILinControl`.
  - If the method returns *Exception*, the component is already used by another program.
- ▶ Close the opened control unit with the method `IDisposable.Dispose` and release access by other applications.

**i** If other interfaces are opened during the closing of the control unit, the current settings remain.

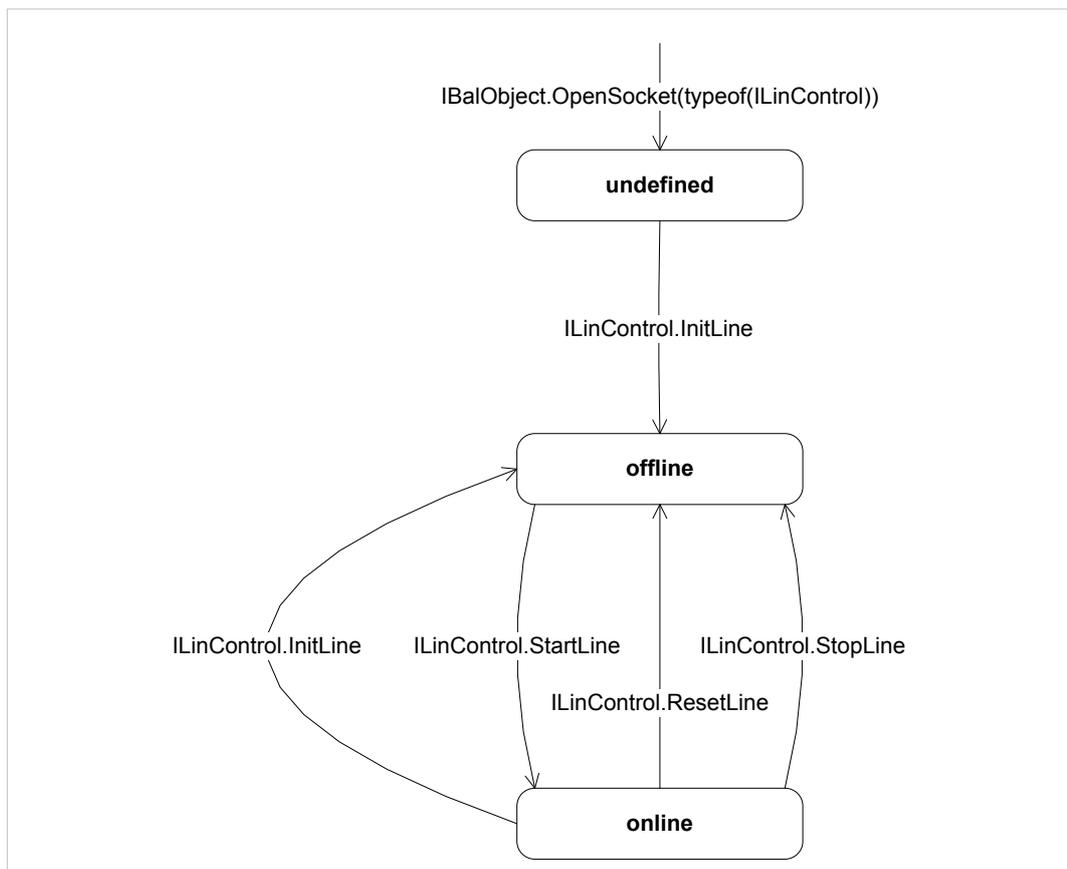

Fig. 30 LIN controller states

### Initializing the Controller

After the first opening of the interface `ILinControl` the controller is in undefined state.

- ▶ To leave the undefined state, call the method `InitLine`.
  - Controller is in state *offline*.
- ▶ Specify the system mode and transmission rate with the method `InitLine`.
  - ▶ Method expects structure `LinInitLine` with values for operating mode and bit rate.
- ▶ Specify the transmission rate in bits per second in field `LinInitLine.Bitrate`.
  - Valid values are between 1000 and 20000 bit/s, resp. between `LinBitrate.MinBitrate` and `LinBitrate.MaxBitrate`.

If the controller supports automatic bit identification, automatic bit identification can be activated with `LinBitrate.AutoRate`.

#### Recommended bit rates:

Slow	Medium	Fast
<code>LinBitrate.Lin2400Bit</code>	<code>LinBitrate.Lin9600Bit</code>	<code>LinBitrate.Lin19200Bit</code>

### Starting and Stopping the Controller

- ▶ To start the LIN controller, call the method `StartLine`.
  - LIN controller is in state *online*.
  - LIN controller is actively connected to bus.
  - Incoming messages are forwarded to all opened and active message monitors.
- ▶ To stop the LIN controller call the method `StopLine`.
  - LIN controller is in state *offline*.
  - Message transfer to the monitor is interrupted and controller is deactivated.
  - In case of an ongoing data transfer of the controller the method waits until the message is transmitted completely over the bus, before the message transmission is stopped.
- ▶ Call method `ResetLine` to shift the controller in state *offline* and to reset the controller hardware.

With calling the method `ResetLine` a faulty message telegram on the bus is possible if an ongoing transmission is interrupted.

Neither `ResetLine` nor `StopLine` delete the content of the receiving FIFOs of a message monitor.

### Transmitting LIN Messages

Messages can be transmitted directly via the method `ILinControl.WriteMessage` or can be registered in a response table in the controller.

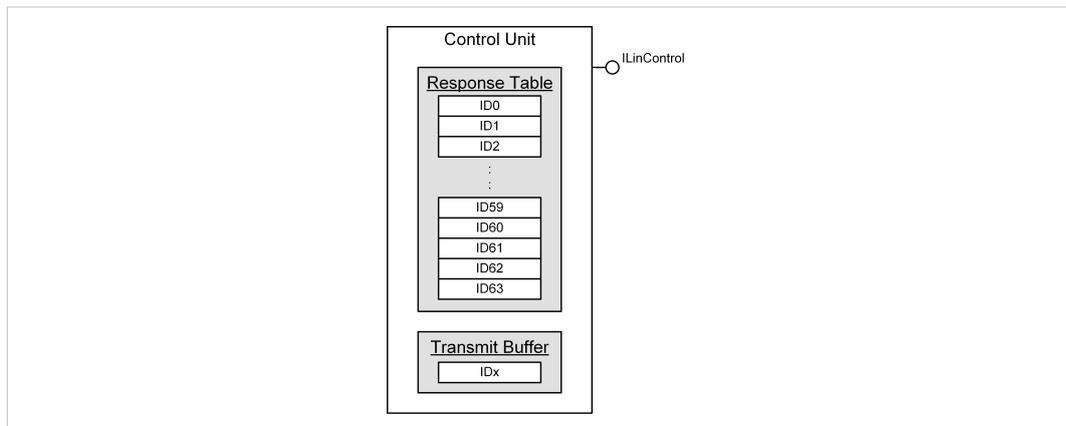

Fig. 31 Internal structure of a control unit

The control unit contains an internal response table with the response data for the IDs transmitted by the master. If the controller detects an ID that is assigned to it and transmitted by the master it transmits the response data entered in the table at the corresponding position automatically to the bus.

To change or update the content of the response table call method `ILinControl.WriteMessage`.

- ▶ In parameter *send* set the value `FALSE`.
  - Message with response data in the data field of structure `LinMessage` is assigned to method in parameter *message*.
- ▶ To clear the response table call the method `ILinControl.ResetLine`.

Data field of structure `LinMessage` contains the response data. The LIN message must be of type `LinMessageType.Data` and must contain an ID in the range 0 to 63.

Irrespective of the operating mode (master or slave) the table must be initialized before the controller is started. It can be updated at any time without stopping the controller.

Transmitting messages directly to the bus with method `ILinControl.WriteMessage`.

- ▶ Set parameter *send* to the value `TRUE`.
  - Message is registered in the transmitting buffer of the controller, instead of the response table.
  - Controller transmits message to bus as soon as it is free.

If the controller is configured as master, control messages `LinMessageType.Sleep`, `LinMessageType.Wakeup` and `LinMessageType.Data` can be directly transmitted. If the controller is configured as slave exclusively `LinMessageType.Wakeup` messages can be directly transmitted. With all other message types the method returns an error code.

A message of type `LinMessageType.Sleep` generates a goto-Sleep frame, a message of type `LinMessageType.Wakeup` a wake-up frame on the bus. For further information see chapter Network Management in LIN specifications.

In the master mode the method `ILinControl.WriteMessage` also serves for transmitting IDs. For this a message of type `LinMessageType.Data` with valid ID and data length, where the flag *IdOnly* is set to `TRUE` is transmitted.

---

Irrespective of the value of the parameter *send* `ILinControl.WriteMessage` always returns immediately to the calling program without waiting for the transmission to be completed. If the method is called before the last transmission is completed or before the transmission buffer is free again, the method returns with a respective error code.

## 7 Interface Description

For a detailed description of the VCI .NET interfaces and classes see installed folder reference *vci4net.chm* in sub-directory *manual*.

**This page intentionally left blank**
